# Foreword

This catalogue contains the standard assortment of SKF rolling bearings typically used in industrial applications. To provide the highest levels of quality and customer service, these products are available worldwide through SKF sales channels. For information about lead times and deliveries, contact your local SKF representative or SKF Authorized Distributor.

The data in this catalogue reflect SKF's state-of-the-art technology and production capabilities as of 2012. The data contained within may differ from that shown in earlier catalogues because of redesign, technological developments, or revised calculation methods. SKF reserves the right to continually improve its products with respect to materials, design and manufacturing methods, some of which are driven by technological developments.

## Getting started

This catalogue contains detailed information about standard SKF rolling bearings, several special engineered products and bearing accessories. Engineered products include motor encoder units, which can measure the speed and direction of rotation, polymer bearings and rolling bearings designed to fulfil additional requirements, such as:

- extreme temperatures
- electrical insulation
- dry lubrication
- insufficient lubrication
- rapid speed changes
- high vibration levels
- oscillating movements

The first section, which contains general technical information, is designed to help the reader select the best, most effective products

for a particular application. In this section, bearing service life, speed capabilities, friction, general design considerations and lubrication are discussed in detail. Installation and maintenance information is also included. More practical information about mounting and maintenance is provided in the *SKF bearing maintenance handbook* (ISBN 978-91-978966-4-1).

## The latest developments

The main content updates compared to the previous catalogue include the addition of Y-bearings and needle roller bearings as well as the following featured products:

### SKF Energy Efficient bearings

To meet the ever-increasing demand to reduce energy consumption, SKF has developed the SKF Energy Efficient (E2) performance class of rolling bearings. SKF E2 bearings are characterized by a frictional moment in the bearing

*SKF Energy Efficient bearings are identified by the designation prefix E2.*

## Foreword

that is at least 30% lower when compared to a same-sized SKF standard bearing.

### High-capacity cylindrical roller bearings

SKF high-capacity cylindrical roller bearings combine the high load carrying capacity of full complement bearings and the high speed capability of bearings with a cage. They are designed for applications such as industrial gearboxes, gearboxes in wind turbines and mining equipment.

*SKF high-capacity cylindrical roller bearing*

### SKF DryLube bearings

SKF DryLube bearings are a new option for extreme temperature applications. They are filled with a dry lubricant, based on graphite and molybdenum disulfide. The dry lubricant can protect the rolling elements and raceways from damage caused by solid contaminants. SKF DryLube bearings provide effective lubrication for high temperature applications, low start-up torque at any temperature and low frictional moment during operation.

*SKF DryLube bearing*

### Polymer ball bearings

Polymer ball bearings are an excellent solution from both a technical and economic perspective, in applications where resistance to moisture or chemicals is essential. Polymer ball bearings use bearing rings or washers made of various polymer materials and balls made of glass, stainless steel or polymers. They are lightweight, self lubricating, quiet running, and resistant to corrosion, chemicals and wear and fatigue.

*Polymer ball bearing*

### SKF ConCentra Y-bearings (insert bearings)

The SKF ConCentra locking technology provides a true concentric fit of the bearing on a shaft, to virtually eliminate fretting corrosion. These bearings are as easy to mount as bearings with grub screw locking.

*SKF ConCentra Y-bearing*

### Grease life calculation for capped deep groove ball bearings

Capped deep groove ball bearings and Y-bearings (insert bearings) are typically greased for life. SKF did extensive research to enable a theoretical approach to estimate the grease life depending on bearing speed, operating temperature, load and other factors.

### Extended assortment for value-added bearings

The assortment of capped bearings, SKF Explorer bearings, electrically insulated bearings and hybrid bearings has been extended.

Grease life estimation for capped bearings

### How to use this catalogue

This catalogue is divided into two main sections: a technical section and a product section. The technical section describes in detail how to select and apply rolling bearings and covers eight main topics marked with printed tabs from A to H. The product section is divided into chapters by product type. Each chapter contains specific information about the bearing type and its optional variants and product tables. Each product chapter is clearly marked by cut tabs with an easily identifiable icon.

Printed and cut tabs simplify navigation

### Find information quickly

The catalogue is designed so that specific information can be found quickly. At the front of the catalogue there is the full table of contents. At the back, there is a product index and a full text index.

A comprehensive text index helps to locate specific information quickly.

## Foreword

### Find product details quickly

A quick way to access detailed product data is via a product table number. Product table numbers are listed in the table of contents at the front of the catalogue, in the table of contents at the start of each product chapter and in the product index at the back of the catalogue.

### Identify products

Product designations for SKF rolling bearings typically contain information about the bearing and additional features. To specify an SKF bearing or to find more information about it, there are three options:

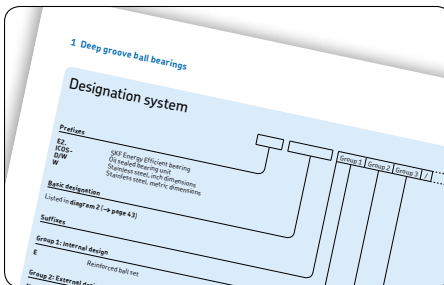

- **Product index**  
The product index at the end of the catalogue lists series designations, relates them to the bearing type and guides the reader to the relevant product chapter and product table.
- **Designation charts**  
Product designations in each product chapter are located on the pages preceding the product tables. These charts identify commonly used designation prefixes and suffixes.
- **Text index**  
The text index at the end of the catalogue contains designation suffixes in alphabetical order. They are printed bold for quick browsing.

### Units of measurement

This catalogue is for global use. Therefore, the predominant units of measurement are in accordance with ISO 80000-1. Exceptionally, imperial units are used when it is required by the product. Unit conversions can be made using the conversion table (→ **page 8**).

For easier use, temperature values are provided in both, °C and °F. Temperature values are typically rounded. Therefore, the two values do not always exactly match when using the conversion formula.

### More SKF rolling bearings

Other rolling bearings, not presented in this catalogue, include:

- super-precision bearings
- ball and roller bearing units
- fixed section ball bearings
- large deep groove ball bearings with filling slots
- large angular contact thrust ball bearings
- tapered roller thrust bearings
- multi-row ball or roller bearings
- split roller bearings
- crossed tapered roller bearings
- slewing bearings
- linear ball bearings
- bearings for inline skates and skateboards
- backing bearings for cluster mills
- indexing roller units for continuous furnaces of sintering plants
- application specific bearings for railway rolling stock
- application specific bearings for cars and trucks
- triple ring bearings for the pulp and paper industry
- bearings for printing press rollers
- bearings for critical aerospace applications

# This is SKF

From one simple but inspired solution to a misalignment problem in a textile mill in Sweden, and fifteen employees in 1907, SKF has grown to become a global industrial knowledge leader. Over the years we have built on our expertise in bearings, extending it to seals, mechatronics, services and lubrication systems. Our knowledge network includes 46 000 employees, 15 000 distributor partners, offices in more than 130 countries, and a growing number of SKF Solution Factory sites around the world.

## Research and development

We have hands-on experience in over forty industries, based on our employees' knowledge of real life conditions. In addition our world-leading experts and university partners who pioneer advanced theoretical research and development in areas including tribology, condition monitoring, asset management and bearing life theory. Our ongoing commitment to research and development helps us keep our customers at the forefront of their industries.

*SKF Solution Factory makes SKF knowledge and manufacturing expertise available locally, to provide unique solutions and services to our customers.*

### Meeting the toughest challenges

Our network of knowledge and experience along with our understanding of how our core technologies can be combined helps us create innovative solutions that meet the toughest of challenges. We work closely with our customers throughout the asset life cycle, helping them to profitably and responsibly grow their businesses.

### Working for a sustainable future

Since 2005, SKF has worked to reduce the negative environmental impact from our own operations and those of our suppliers. Our continuing technology development introduced the SKF BeyondZero portfolio of products and services which improve efficiency and reduce energy losses, as well as enable new technologies harnessing wind, solar and ocean power. This combined approach helps reduce the environmental impact both in our own operations and in our customers'.

*Working with SKF IT and logistics systems and application experts, SKF Authorized Distributors deliver a valuable mix of product and application knowledge to customers worldwide.*

# SKF – the knowledge engineering company

## Our knowledge – your success

*SKF Life Cycle Management is how we combine our technology platforms and advanced services, and apply them at each stage of the asset life cycle, to help our customers to be more successful, sustainable and profitable.*

### Working closely with you

Our objective is to help our customers improve productivity, minimize maintenance, achieve higher energy and resource efficiency, and optimize designs for long service life and reliability.

### Innovative solutions

Whether the application is linear or rotary or a combination of the two, SKF engineers can work with you at each stage of the asset life cycle to improve machine performance by looking at the

entire application. This approach doesn't just focus on individual components like bearings or seals. It looks at the whole application to see how each component interacts with the next.

### Design optimization and verification

SKF can work with you to optimize current or new designs with proprietary 3-D modeling software that can also be used as a virtual test rig to confirm the integrity of the design.

### **Bearings**

*SKF is the world leader in the design, development and manufacture of high performance rolling bearings, plain bearings, bearing units and housings.*

### **Machinery maintenance**

*Condition monitoring technologies and maintenance services from SKF can help minimize unplanned downtime, improve operational efficiency and reduce maintenance costs.*

### **Sealing solutions**

*SKF offers standard seals and custom engineered sealing solutions to increase uptime, improve machine reliability, reduce friction and power losses, and extend lubricant life.*

### **Mechatronics**

*SKF fly-by-wire systems for aircraft and drive-by-wire systems for off-road, agricultural and forklift applications replace heavy, grease or oil consuming mechanical and hydraulic systems.*

### **Lubrication solutions**

*From specialized lubricants to state-of-the-art lubrication systems and lubrication management services, lubrication solutions from SKF can help to reduce lubrication related downtime and lubricant consumption.*

### **Actuation and motion control**

*With a wide assortment of products – from actuators and ball screws to profile rail guides – SKF can work with you to solve your most pressing linear system challenges.*

# Selecting rolling bearings

A bearing system consists of more than just bearings. Associated components like the shaft and housings are integral parts of the overall system. The lubricant and sealing elements also play a critical role. To maximize bearing performance, the correct amount of an appropriate lubricant must be present to reduce friction in the bearing and protect it from corrosion. Sealing elements are important, because they keep the lubricant in and contaminants out of the bearing. This is particularly important because cleanliness has a profound effect on bearing service life – which is why SKF manufactures and sells a wide range of industrial seals and lubrication systems.

There are a number of factors that go into the bearing selection process. Understanding the dynamic behaviour of the application is probably one of the most important. Dynamic behaviour, in this case, means:

- available space
- loads (magnitude and direction)
- misalignment
- precision and stiffness
- speeds
- operating temperature
- vibration levels
- contamination levels
- lubrication type and method

Once the dynamic behaviour has been established, a suitable bearing type and size can be selected. However, during the bearing selection process there are several other factors that need to be considered:

- a suitable form and design of other components of the arrangement
- appropriate fits and bearing internal clearance or preload
- holding devices
- adequate seals
- the type and quantity of lubricant
- installation and removal methods

When designing an application, every decision affects the performance, reliability and economy of the bearing system.

As the leading bearing supplier, SKF manufactures a large number of bearing types, series, designs, variants and sizes. The most common of them are introduced under *Bearing types and designs* (→ page 26). There are also bearings that are not included in this catalogue. Information about most of these bearings is provided in special catalogues or online at [skf.com/bearings](http://skf.com/bearings).

In this section and in sections B through H, the designer of a bearing system can find the necessary basic information presented in the order in which it is generally required. Obviously, it is impossible to include all the information needed to cover every conceivable application. For this reason, in many places, reference is made to the SKF application engineering service. This technical service can perform complex calculations, diagnose and solve bearing performance issues, and help with the bearing selection process. SKF also recommends this service to anyone working to improve the performance of their application.

The information contained in this section and in sections B through H is general and applies to most rolling bearings. Information specific to one bearing type is provided in the relevant product chapter. Additional catalogues and brochures covering specific application areas are available on request. Detailed information about almost all SKF rolling bearings, bearing units, housings, plain bearings and seals is available online at [skf.com/bearings](http://skf.com/bearings).

It should be noted that the values listed in the product tables for load and speed ratings as well as for the fatigue load limit are heavily rounded.

## Terminology

Some frequently used bearing terms are explained here. For a detailed collection of bearing-specific terms and definitions, refer to ISO 5593 Rolling bearings – Vocabulary.

## Symbols

Symbols used in this catalogue are mainly in accordance with ISO standards. Most common symbols for bearing boundary dimensions are shown in **fig. 1**. Other symbols are listed below. All symbols can be used with a subscript to identify specifications.

- A = speed factor  
=  $n \cdot d_m$  [mm/min]
- C = bearing load rating [kN]
- $d_m$  = bearing mean diameter [mm]  
=  $0,5 (d + D)$
- F = actual bearing load [kN]
- L = life, typically in million revolutions or operating hours
- n = rotational speed [r/min]
- P = equivalent bearing load [kN]
- $P_u$  = fatigue load limit [kN]
- $\eta_c$  = factor for contamination level
- $\kappa$  = viscosity ratio: actual versus required
- $\nu$  = oil viscosity [mm<sup>2</sup>/s]

## Cages

With the exception of full complement bearings, all rolling bearings contain a cage. The number of cages depends on the number of ball or roller sets within the bearing and on the cage design. The primary purposes of a cage are:

- Keeping the rolling elements at a proper distance from each other to reduce the frictional moment and frictional heat in the bearing.
- Keeping the rolling elements evenly spaced to optimize load distribution and enable quiet and uniform operation.
- Guiding the rolling elements in the unloaded zone, to improve the rolling conditions and to prevent damaging sliding movements.
- Retaining the rolling elements of separable bearings when one bearing ring is removed during mounting or dismounting.

Cages are mechanically stressed by frictional, strain and inertial forces. They can also be chemically stressed by certain lubricants, lubricant additives or by-products of their ageing, organic solvents or coolants. Therefore, the design and material of a cage have a significant influence on the suitability of a rolling bearing for a particular application. Therefore, SKF has developed a variety of cages, made of different materials, for the different bearing types.

In each product chapter, information about standard cages and possible alternatives is provided. If a bearing with a non-standard cage is required, check availability prior to ordering.

Cages can be classified according to the manufacturing process and material group into:

- stamped metal cages
- machined metal cages
- polymer cages

Fig. 6

### Stamped metal cages

Stamped metal cages for SKF bearings (→ fig. 6) are generally made of sheet steel and with some exceptions, of sheet brass. Depending on the bearing type, the following stamped metal cages are available:

- a ribbon-type cage (a)
- a riveted cage (b)
- a snap-type cage (c)
- a window-type cage (d)

Stamped metal cages are lightweight. They provide ample space inside the bearing to maximize the effects of the lubricant.

Fig. 7

**Machined metal cages**

Machined metal cages for SKF bearings (→ fig. 7) are made of brass, steel or light alloy. Depending on the bearing type, design and size, the following machined metal cages are available:

- a two-piece machined riveted metal cage (a)
- a two-piece machined metal cage with integral rivets (b)
- a one-piece machined window-type metal cage (c)
- a double prong-type machined metal cage (d)

Machined metal cages, which generally permit higher speeds, are typically used when forces, other than pure rotational forces, are super-imposed on the cage.

**Polymer cages**

Polymer cages for SKF bearings (→ fig. 8) are injection moulded. SKF also manufactures a fabric reinforced phenolic resin cage, but only for super-precision bearings, which are not included in this catalogue. Depending on the bearing type, design and size, the following polymer cages are available:

- a polymer window-type cage (a)
- a polymer snap-type cage (b)

Polymer cages are characterized by a favourable combination of strength and elasticity. The good sliding properties of the polymer on

Fig. 8

lubricated steel surfaces and the smoothness of the cage surfaces in contact with the rolling elements produce little friction so that frictional heat and wear in the bearing are minimized. The low density of the material means that the inertial forces generated by the cage are minor. The excellent running properties of polymer cages under poor lubrication conditions permit continued operation of the bearing for some time without the risk of seizure and secondary damage.

### Cage guidance

Stamped metal cages are typically guided by the rolling elements.

Depending on the bearing type and design, machined metal and polymer cages are radially centred (→ **fig. 9**) either on:

- the rolling elements (a)
- the inner ring (shoulder(s)) (b)
- the outer ring (shoulder(s)) (c)

Cages guided by the rolling elements permit the lubricant to enter the bearing easily.

Ring guided cages, which provide more precise guidance, are typically used when bearing arrangements must accommodate high speeds, frequent, rapid accelerations or high vibration levels. Suitable steps must be taken to provide a sufficient supply of lubricant to the guiding surfaces of the cage. For higher speeds, SKF recommends oil lubrication (→ *Lubrication*, **page 239** and/or relevant product chapter).

### Materials

For information about materials used for cages, refer to *Cage materials* (→ **page 152**).

Fig. 9

## Boundary dimensions

Boundary dimensions are the main dimensions of a bearing (→ **fig. 10**). They comprise:

- the bore diameter ( $d$ )
- the outside diameter ( $D$ )
- the width or height ( $B$ ,  $C$ ,  $T$  or  $H$ )
- the chamfer dimensions ( $r$ )

The boundary dimensions for standard metric bearings are contained in the general plans as specified in ISO (International Organization for Standardization) standards:

- ISO 15 for radial rolling bearings, except Y-bearings, some types of needle roller bearings and tapered roller bearings
- ISO 104 for thrust bearings
- ISO 355 for tapered roller bearings

## ISO general plans

The ISO general plans for boundary dimensions of radial bearings contain a progressive series of standardized outside diameters for every standard bore diameter arranged in diameter series 7, 8, 9, 0, 1, 2, 3 and 4 (in order of increasing outside diameter). Within each diameter series different width series have also been established (width series 8, 0, 1, 2, 3, 4, 5 and 6 in order of increasing width).

The height series for thrust bearings (height series 7, 9, 1 and 2 in order of increasing height) corresponds to the width series for radial bearings.

Dimension series are formed by combining the number for the width or height series with the number for the diameter series (→ **fig. 11**).

In the ISO general plan for single row metric tapered roller bearings (ISO 355), the boundary dimensions are grouped for certain ranges of the contact angle  $\alpha$ , known as the angle series (angle series 2, 3, 4, 5, 6 and 7 in order of increasing angle). Based on the relationship between the bore and outside diameter, and between the total bearing width and the cross-sectional height, diameter and width series have also been established. Here, a dimension series is obtained by combining an angle series with a diameter and a width series (→ **fig. 12**). The dimension series consists of a number for the angle series and two letters. The first letter identifies the diameter series; the second identifies the width series.

With very few exceptions, the bearings in this catalogue comply with the ISO general

Fig. 10

plans. Experience has shown that the requirements of the vast majority of bearing applications can be met using bearings with these standardized dimensions. Following ISO standards for the boundary dimensions is a prerequisite for interchangeability of bearings. Specific information about compliance to dimension standards is provided in each product chapter.

### General plans for inch bearings

A large group of bearings with inch dimensions are inch tapered roller bearings. The dimensions of these bearings are in accordance with AFBMA Standard 19 (ANSI B3.19). ANSI/ABMA Standard 19.2 has replaced this standard, but does not include dimensions.

In addition to the inch tapered roller bearings, some inch ball bearings and cylindrical roller bearings are also available, but not listed in this catalogue.

Fig. 12

## Basic bearing designation system

The designations of most SKF rolling bearings follow a designation system. The complete bearing designation may consist of a basic designation with or without one or more supplementary designations (→ **diagram 1**). The complete designation is always marked on the bearing package, whereas the marking on the bearing may be incomplete or deviate from the designation.

The basic designation identifies:

- the bearing type
- the basic design
- the boundary dimensions

Prefixes and suffixes identify bearing components or variants having a design and/or feature(s) that differ in some respect from the basic design.

### Basic designations

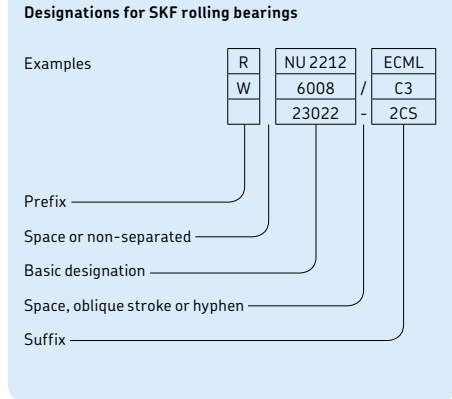

A basic designation typically contains three to five digits. Some products, like cylindrical roller bearings, can have a combination of alphanumeric characters. The basic designation system is shown in **diagram 2**. The number and letter combinations have the following meaning:

- The first digit or letter or combination of letters identifies the bearing type and eventually a basic variant.
- The following two digits identify the ISO dimension series. The first digit indicates the width or height series (dimensions B, T or H). The second digit identifies the diameter series (dimension D).
- The last two digits of the basic designation identify the size code of the bearing bore. The size code multiplied by 5 gives the bore diameter (d) in mm.

The most important exceptions in the basic bearing designation system are:

- 1 In a few cases the digit for the bearing type or the first digit of the dimension series identification is omitted. These digits are shown in brackets in **diagram 2**.

Diagram 1

- 2 Bearings with a bore diameter of 10, 12, 15 or 17 mm have the following size code identifications:

00 = 10 mm  
 01 = 12 mm  
 02 = 15 mm  
 03 = 17 mm

- 3 For bearings with a bore diameter < 10 mm, or ≥ 500 mm, the bore diameter is generally given in millimetres (uncoded). The size identification is separated from the rest of the bearing designation by an oblique stroke, e.g. 618/8 (d = 8 mm) or 511/530 (d = 530 mm). This is also true of standard bearings in accordance with ISO 15 that have a bore diameter of 22, 28 or 32 mm, e.g. 62/22 (d = 22 mm).
- 4 For some bearings with a bore diameter < 10 mm, such as deep groove, self-aligning and angular contact ball bearings, the bore diameter is also given in millimetres (uncoded) but is not separated from the series designation by an oblique stroke, e.g. 629 or 129 (d = 9 mm).
- 5 Bore diameters that deviate from the standard bore diameter of a bearing are uncoded and given in millimetres up to three decimal places. This bore diameter identification is part of the basic designation and is separated from the basic designation by an oblique stroke, e.g. 6202/15.875 (d = 15,875 mm =  $\frac{5}{8}$  in).

**Series designations**

Each standard bearing belongs to a given bearing series, which is identified by the basic designation without the size identification. Series designations often include a suffix A, B, C, D or E or a combination of these letters. These letters are used to identify differences in internal design.

The most common series designations are shown in **diagram 2** (→ **page 43**) above the illustrations. The digits in brackets are omitted in the series designation.

**Prefixes and suffixes**

Prefixes and suffixes provide additional information about the bearing. Prefixes and suffixes and their significance are explained in the relevant product chapter.

**Prefixes**

Prefixes are mainly used to identify components of a bearing. They can also identify bearing variants.

**Suffixes**

Suffixes identify designs or variants, which differ in some way from the original design or from the current basic design. The suffixes are divided into groups. When more than one special feature is to be identified, suffixes are provided in the order shown in **diagram 3**.

**Bearing designations not covered by the basic bearing designation system****Y-bearings (insert bearings)**

The designations for Y-bearings differ somewhat from the system described above and are covered in the relevant product chapter.

**Needle roller bearings**

The designations for needle roller bearings do not fully follow the system described above and are covered in the relevant product chapter.

**Tapered roller bearings**

The designations for metric tapered roller bearings follow either the system described above or a designation system established by ISO in 1977 (→ ISO 355). Inch tapered roller bearings are designated in accordance with the relevant ANSI/ABMA standard.

The designation system for tapered roller bearings is explained in the relevant product chapter.

**Customized bearings**

Bearings designed to meet a specific customer requirement are typically designated by a drawing number. The drawing number does not provide any information about the bearing.

**Other rolling bearings**

Rolling bearings not covered in this catalogue, such as super-precision bearings, thin section bearings, slewing bearings or linear bearings follow designation systems, which can differ significantly from the system described above. Information about these designation systems is provided in the relevant catalogues.

## Basic selection criteria

Each bearing type displays characteristic properties, based on its design, which makes it more, or less, appropriate for a given application. For example, deep groove ball bearings can accommodate normal radial loads as well as axial loads. These low-friction bearings, which are also available in the SKF Energy Efficient performance class, can be manufactured with a high degree of running accuracy and are available in quiet running variants. Therefore, they are preferred for small and medium-size electric motors.

Spherical and toroidal roller bearings can accommodate very heavy loads and are self-aligning. These properties make them popular for applications, where there are heavy loads, shaft deflections and misalignment.

In many cases, however, several factors have to be considered and weighed against each other when selecting a bearing, so that no general rules can be given. The information provided here should serve to indicate the most important factors to be considered when selecting a standard bearing:

- available space
- loads
- misalignment
- precision
- speed
- friction
- quiet running
- stiffness
- axial displacement
- mounting and dismounting
- sealing solutions

The total cost of a bearing system and inventory considerations can also influence bearing selection.

Some of the most important criteria to consider, when designing a bearing arrangement, are covered in depth in separate sections of this catalogue. These include load carrying capacity and life, friction, permissible speeds, bearing internal clearance or preload, lubrication and sealing solutions.

Detailed information on the individual bearing types, including their characteristics and the available designs, is provided in each product chapter.

Fig. 14

Fig. 15

This catalogue does not cover the complete SKF rolling bearings assortment. Specific catalogues and brochures are available for bearings not covered here. For additional information, contact SKF.

### Available space

In many cases, the principal dimensions of a bearing are predetermined by the machine's design. For example, the shaft diameter determines the bearing bore diameter.

For small-diameter shafts all types of ball bearings can be used, the most popular being deep groove ball bearings; needle roller bearings are also suitable (→ **fig. 13**). For large-diameter shafts, cylindrical, tapered, spherical and toroidal roller bearings and deep groove ball bearings are available (→ **fig. 14**).

When radial space is limited, bearings with a low cross-sectional height, should be chosen. These can include needle roller and cage assemblies, drawn cup needle roller bearings and needle roller bearings with or without an inner ring (→ **fig. 15**). Other bearing types in the 8 or 9 diameter series can also be used.

When axial space is limited, narrow series cylindrical roller bearings and deep groove ball bearings can be used to accommodate radial or combined loads (→ **fig. 16**). Combined needle roller bearings (→ **fig. 17**) can also be used. For purely axial loads, needle roller and cage thrust assemblies (with or without washers) as well as thrust ball bearings and cylindrical roller thrust bearings can be used (→ **fig. 18**).

Fig. 17

Fig. 18

## Bearing basics

### Loads

#### Magnitude of load

The magnitude of the load is one of the factors that usually determines the size of the bearing. Generally, roller bearings are able to support heavier loads than similar-sized ball bearings (→ **fig. 19**). Bearings with a full complement of rolling elements can accommodate heavier loads than corresponding bearings with a cage. Ball bearings are typically used in applications where loads are light to normal. Roller bearings are used in applications where loads are heavier.

#### Direction of load

##### Radial loads

NU and N design cylindrical roller bearings, needle roller bearings and toroidal roller bearings can only support pure radial loads (→ **fig. 20**). All other radial bearings can accommodate some axial loads in addition to radial loads (→ *Combined loads*, **page 50**).

##### Axial loads

Thrust ball bearings and four-point contact ball bearings (→ **fig. 21**) are suitable for light or normal loads that are purely axial. Single direction thrust ball bearings can only accommodate axial loads in one direction. For axial loads acting in both directions, double direction thrust ball bearings are needed.

Fig. 19

Fig. 20

Fig. 21

Angular contact thrust ball bearings can support normal axial loads at high speeds. Here, the single direction bearings can also accommodate simultaneously acting radial loads, while double direction bearings are normally used only for purely axial loads (→ **fig. 22**).

For normal to heavy loads that are purely axial and act in one direction only, needle roller thrust bearings, cylindrical and tapered roller thrust bearings are suitable. Spherical roller thrust bearings (→ **fig. 23**) can accommodate axial loads in one direction only as well as radial loads. For heavy alternating axial loads, two cylindrical roller thrust bearings or two spherical roller thrust bearings can be mounted in pairs.

## Bearing basics

### Combined loads

A combined load consists of a radial and axial load acting simultaneously. The ability of a bearing to accommodate an axial load is determined by the contact angle  $\alpha$ . The greater the angle, the higher the axial load carrying capacity of the bearing. An indication of this is given by the calculation factor  $Y$ , which becomes smaller as the contact angle  $\alpha$  increases. The values of the angle  $\alpha$  or the factor  $Y$  are listed in the relevant product chapter.

The axial load carrying capacity of a deep groove ball bearing depends on its internal design and the operational internal clearance (→ *Deep groove ball bearings*, **page 295**).

For combined loads, single and double row angular contact ball bearings and single row tapered roller bearings are most commonly used, although deep groove ball bearings and spherical roller bearings are suitable (→ **fig. 24**). In addition, self-aligning ball bearings and NJ and NUP design cylindrical roller bearings as well as NJ and NU design cylindrical roller bearings with HJ angle rings can be used for combined loads when the axial component is relatively small (→ **fig. 25**).

Single row angular contact ball bearings, single row tapered roller bearings, NJ design cylindrical roller bearings, NU design cylindrical roller bearings with an HJ angle ring and spherical roller thrust bearings can accommodate axial loads in one direction only. For axial loads that alternate direction, these bearings must be combined with a second bearing. For this reason, universally matchable angular contact ball bearings and matched sets of tapered roller bearings are available (→ *Bearings for universal matching*, **page 477**, or *Matched bearings*, **page 802**).

When the axial component of the combined load is significantly large, a second bearing, free of radial load may be necessary. In addition to thrust bearings, some radial bearings, e.g. deep groove ball bearings or four-point contact ball bearings (→ **fig. 26**) are suitable. To make sure that the bearing is subjected to a purely axial load, the bearing outer ring must be mounted with radial clearance.

#### Moment loads

When a load acts eccentrically on a bearing, a tilting moment occurs. Double row bearings, e.g. deep groove and angular contact ball bearings, can accommodate tilting moments, but paired single row angular contact ball bearings and tapered roller bearings arranged back-to-back, are more suitable (→ **fig. 27**).

Fig. 26

A

Fig. 27

### Misalignment

Angular misalignment between the shaft and housing occurs when the shaft deflects (bends) under the operating load. Misalignment can also occur when the bearings are too far apart.

Rigid bearings, i.e. deep groove ball bearings and cylindrical roller bearings can accommodate only a few minutes of misalignment without damaging the bearing. Self-aligning bearings, e.g. self-aligning ball bearings, spherical roller bearings, toroidal roller bearings and spherical roller thrust bearings (→ **fig. 28**), can accommodate shaft deflections as well as initial misalignment resulting from machining or mounting errors. Values for the permissible misalignment are listed in the

relevant product chapter. If the expected misalignment exceeds the permissible values, contact the SKF application engineering service.

Thrust ball bearings with sphered housing and seat washers, Y-bearing units and alignment needle roller bearings (→ **fig. 29**) can compensate for initial misalignment arising from machining or mounting errors.

Fig. 28

Fig. 29

## Precision

When dealing with rolling bearings, precision is described by tolerance classes for running accuracy and dimensional accuracy.

Each product chapter provides information about the tolerance classes to which the bearings are manufactured. SKF manufactures a comprehensive assortment of super-precision bearings, including single row angular contact ball bearings, single and double row cylindrical roller bearings and single and double direction angular contact thrust ball bearings. For information about super-precision bearings, refer to the product information available online at [skf.com/super-precision](https://skf.com/super-precision).

## Speed

The permissible operating temperature puts limits on the speed at which rolling bearings can be operated. Bearing types that operate with low friction and generate low frictional heat are therefore the most suitable for high-speed operation.

The highest speeds can be achieved with deep groove ball bearings and self-aligning ball bearings (→ **fig. 30**) when loads are purely radial. Angular contact ball bearings (→ **fig. 31**) are typically used when there are combined loads. This is particularly true for super-precision angular contact ball bearings and deep groove ball bearings with ceramic rolling elements, also referred to as hybrid bearings.

Because of their design, thrust bearings cannot accommodate speeds as high as radial bearings.

Fig. 30

Fig. 31

A

### Friction

Rolling bearings are also known as “anti-friction bearings”, but of course, some frictional losses occur in the bearing. One contributing factor to rolling friction in a bearing is the result of elastic deformation of the rolling elements and raceways under load. Other sources include, but are not limited to, the sliding friction that occurs between the rolling elements and cage, flanges and guide rings, and between seals and their counterface. Friction in the lubricant also contributes to the total frictional moment. The frictional moment of SKF rolling bearings can be calculated (→ *Friction*, page 97).

In general, ball bearings have a lower frictional moment than roller bearings. If very low friction is an essential requirement, SKF Energy Efficient (E2) bearings should be considered. The frictional moment in SKF E2 bearings is at least 30% lower than a similar-sized SKF standard bearing. SKF E2 bearings are available for several bearing types:

- single row deep groove ball bearings
- Y-bearings (insert bearings)
- double row angular contact ball bearings
- single row tapered roller bearings
- spherical roller bearings
- cylindrical roller bearings

### Quiet running

In certain applications, e.g. small electric motors for household appliances or office machinery, the noise level in operation is an important factor and can influence the choice of bearing type. SKF manufactures a deep groove ball bearing variant specifically for these types of applications.

### Stiffness

The stiffness of a rolling bearing is characterized by the magnitude of the elastic deformation (resilience) in the bearing under load. Generally, this deformation is very small and can be neglected. However, in applications like machine tool spindles and transmission differentials, stiffness is a key operational parameter.

Because of the contact conditions between the rolling elements and raceways, roller bearings, e.g. cylindrical or tapered roller bearings (→ **fig. 32**), have a higher degree of stiffness than ball bearings. Bearing stiffness can be further enhanced by applying a preload (→ *Bearing preload*, page 214).

Fig. 32

## Axial displacement

Shafts, or other rotating machine components, are generally supported by a locating and a non-locating bearing (→ *Bearing systems, page 160*).

The bearing in the locating position must be able to locate the shaft axially in both directions. The most suitable bearings for the locating position are those bearings that can accommodate combined loads, or can provide axial guidance in combination with a second bearing.

Non-locating bearings must accommodate axial movement of the shaft, to avoid induced axial loads when, for example, thermal elongation of the shaft occurs. Bearings suitable for the non-locating position include needle roller bearings and NU and N design cylindrical roller bearings (→ **fig. 33**). NJ design cylindrical roller bearings and some full complement design cylindrical roller bearings can also be used.

In applications where the required axial displacement is relatively large and misalignment may also occur, a CARB toroidal roller bearing is an excellent choice as the non-locating bearing (→ **fig. 34**).

All of these bearings accommodate axial displacement between the shaft and the housing, within the bearing. Values for the permissible axial displacement within the bearing are listed in the relevant product tables.

If non-separable bearings, e.g. deep groove ball bearings or spherical roller bearings (→ **fig. 35**) are used as non-locating bearings, one of the bearing rings must have a loose fit (→ *Radial location of bearings, page 165*).

Fig. 33

Fig. 34

Fig. 35

### Mounting and dismounting

#### Cylindrical bore

Bearings with a cylindrical bore are easier to mount and dismount if they are separable, particularly if interference fits are required for both rings. Separable bearings are also preferable if frequent mounting and dismounting are required, because the ring with the rolling element and cage assembly of these separable bearings can be fitted independently of the other ring, e.g. four-point contact ball bearings, cylindrical, needle and tapered roller bearings (→ **fig. 36**), as well as ball and roller thrust bearings.

#### Tapered bore

Bearings with a tapered bore (→ **fig. 37**) can be mounted easily on a tapered shaft seat or on a cylindrical shaft seat using an adapter or withdrawal sleeve (→ **fig. 38**).

Fig. 36

Fig. 37

Fig. 38

## Bearing basics

### Sealing solutions

To keep lubricant in and contaminants out of the bearing, SKF supplies bearings capped with integral seals or shields:

- shields (→ **fig. 39**)
- non-contact seals (→ **fig. 40**)
- low-friction seals (→ **fig. 41**)
- contact seals (→ **fig. 42**)

These bearings can provide cost-effective and space-saving solutions for many applications. Capped bearings are available for different bearing types:

- deep groove ball bearings
- angular contact ball bearings
- self-aligning ball bearings
- cylindrical roller bearings
- needle roller bearings
- spherical roller bearings
- CARB toroidal roller bearings
- track runner bearings
- Y-bearings (insert bearings)

Bearings capped on both sides are typically lubricated for the life of the bearing and should not be washed or relubricated. They are filled with the appropriate amount of high-quality grease under clean conditions.

### A systems approach to bearing selection

In the SKF life rating equation, the stresses resulting from external loads are considered together with the tribological stresses in the rolling contact area. Understanding the influence of these combined stress systems on bearing life enables a more accurate prediction of how a bearing will perform in its application.

Due to its complexity, a detailed description of the theory is beyond the scope of this catalogue. Therefore, a simplified approach is presented under *SKF rating life* (→ **page 64**). This enables users to fully exploit bearing life potential, to undertake controlled downsizing, and to recognize the influence of lubrication and contamination on bearing service life.

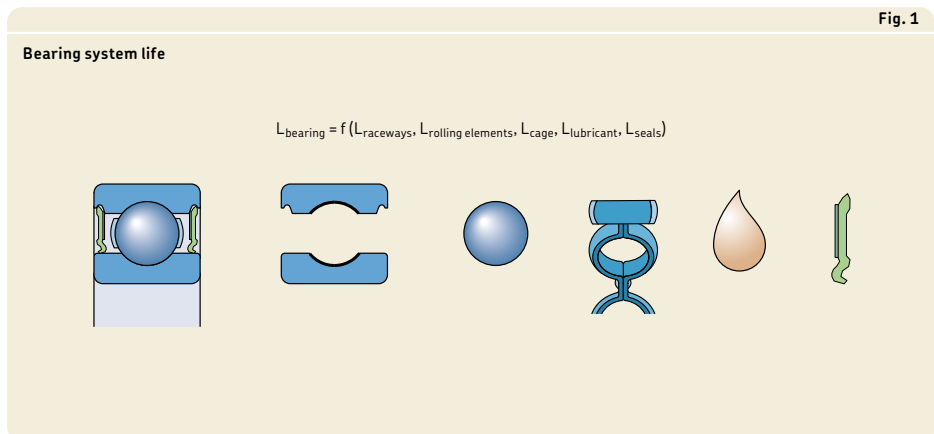

### Bearing system life

Metal fatigue of the rolling contact surfaces is a well-known failure mode for rolling bearings. Metal fatigue can be the result of a variety of factors including but not limited to excessive frictional heat, poor or contaminated lubrication conditions, and heavy external and/or indeterminate loads.

Therefore, a criterion based on raceway fatigue is generally sufficient for the selection and sizing of a rolling bearing for a given application. International standards such as ISO 281 are based on metal fatigue of the rolling contact surfaces. Nevertheless, it is import-

ant to remember that the complete bearing can be viewed as a system in which the life of each component, i.e. rolling elements, raceways, cage, lubricant and seals, when present, contributes equally and in some cases dictates the effective endurance of the bearing (→ **fig. 1**).

In the different sections of this catalogue, references are made to relevant aspects of the strength and suitability of other components of the bearing viewed as a system that need to be checked to ensure the best performance.

# Bearing life and load ratings

## Bearing life definition

The life of a rolling bearing is expressed as the number of revolutions or the number of operating hours at a given speed that the bearing is capable of enduring before the first sign of metal fatigue (spalling) occurs on a raceway of the inner or outer ring or a rolling element.

Under controlled laboratory conditions, seemingly identical bearings operating under identical conditions have different individual endurance lives. A clearer definition of the term “bearing life” is therefore essential to calculate bearing size. All information presented by SKF with regard to load ratings is based on the life that 90% of a sufficiently large group of apparently identical bearings can be expected to attain or exceed.

The rated life based on the above definition has to satisfy the requisite life expectations of the bearing application. In the absence of previous experience, guidelines regarding specification life of different bearing applications are provided in **tables 9 and 10 (→ page 83)**.

Due to the statistical nature of bearing life, it must be pointed out that the observed time to failure of an individual bearing installed in an application can be related to its rated life only if the failure probability, of that particular bearing, can be determined in relation to the general population of bearings running under similar conditions. For instance, if a bearing failure is observed in a bearing fan application counting a total of two hundred installed bearings working under similar conditions, this represent a failure probability of just 0,5%, thus a reliability for the installed application of 99,5%.

Several investigations performed throughout the years regarding the failures of bearings used in a variety of applications have shown that in a very large population (several million bearings), the observed failures are a relatively rare event and not directly related to typical raceway spalling. This shows that the design guidelines based on 90% reliability and the use of static and dynamic safety factors can lead to robust bearing solutions in which typical fatigue failures are in general avoided. Indeed, observed field failures are mostly related to abrasive wear, moisture, corrosion, improper installation, improper shaft/housing

fits, skidding of rolling elements, unforeseen contamination or related to failure of the cage, of the sealing or of the lubrication system.

## Load ratings

A bearing is typically selected on the basis of its load rating relative to the applied loads and the requirements regarding bearing life and reliability. Values for the basic dynamic load rating C and the basic static load rating C<sub>0</sub> are listed in the product tables.

Both dynamic and static bearing load conditions should be independently verified and should include any heavy, short duration shock loads that may occur on rare occasions.

## Dynamic load ratings

The basic dynamic load rating C is used for life calculations involving dynamically stressed bearings, i.e. bearings that rotate under load. It expresses the bearing load that will result in an ISO 281 basic rating life of 1 000 000 revolutions. It is assumed that the load is constant in magnitude and direction and is radial for radial bearings and axial, centrally acting, for thrust bearings.

The basic dynamic load ratings for SKF bearings are determined in accordance with the procedures outlined in ISO 281. The load ratings provided in this catalogue apply to chromium steel bearings, heat-treated to a minimum hardness of 58 HRC, and operating under normal conditions. An exception to this are polymer bearings (→ **page 1247**).

SKF Explorer performance class bearings have undergone, among other things, material and manufacturing improvements that require adjusted factors to calculate the dynamic load ratings in accordance with ISO 281.

## Selecting bearing size

### Static load ratings

The basic static load rating as defined in ISO 76 corresponds to a calculated contact stress at the centre of the most heavily loaded rolling element / raceway contact. The contact stress values are:

- 4 600 MPa for self-aligning ball bearings
- 4 200 MPa for all other ball bearings
- 4 000 MPa for all roller bearings

This stress produces a total permanent deformation of the rolling element and raceway, which is approximately 0,0001 of the rolling element diameter. The loads are purely radial for radial bearings and centrally acting axial loads for thrust bearings.

The basic static load rating  $C_0$  is used under the following conditions:

- very slow rotational speeds ( $n < 10$  r/min)
- very slow oscillating movements
- stationary bearings under load for extended periods

Verification of static bearing loads is performed by checking the static safety factor of the application, which is defined as

$$s_0 = \frac{C_0}{P_0}$$

where

$s_0$  = static safety factor

$C_0$  = basic static load rating [kN]

$P_0$  = equivalent static bearing load [kN]

The maximum load that can occur on a bearing should be used when calculating the equivalent static bearing load. For additional information about the recommended values for the safety factor and its calculation, refer to *Selecting bearing size using static load carrying capacity* (→ page 87).

## Selecting bearing size using the life equations

### Basic rating life

The basic rating life of a bearing in accordance with ISO 281 is

$$L_{10} = \left( \frac{C}{P} \right)^p$$

If the speed is constant, it is often preferable to calculate the life expressed in operating hours using

$$L_{10h} = \frac{10^6}{60 n} L_{10}$$

where

$L_{10}$  = basic rating life (at 90% reliability) [million revolutions]

$L_{10h}$  = basic rating life (at 90% reliability) [operating hours]

$C$  = basic dynamic load rating [kN]

$P$  = equivalent dynamic bearing load [kN] (→ page 85)

$n$  = rotational speed [r/min]

$p$  = exponent of the life equation

– for ball bearings,  $p = 3$

– for roller bearings,  $p = 10/3$

### SKF rating life

For modern high quality bearings, the basic rating life can deviate significantly from the actual service life in a given application. Service life in a particular application depends on a variety of influencing factors including lubrication, the degree of contamination, proper installation and other environmental conditions.

Therefore, ISO 281 uses a modified life factor to supplement the basic rating life. The SKF life modification factor  $a_{SKF}$  applies the same concept of a fatigue load limit  $P_u$  as used in ISO 281. Values of  $P_u$  are listed in the product tables. Like ISO 281, the SKF life modification factor  $a_{SKF}$  takes the lubrication conditions (viscosity ratio  $\kappa$ , → page 71) and a factor  $\eta_c$  (→ page 74) for the contamination level into

consideration to reflect the operating conditions using

$$L_{nm} = a_1 a_{SKF} L_{10} = a_1 a_{SKF} \left(\frac{C}{P}\right)^p$$

If the speed is constant, the life can be expressed in operating hours using

$$L_{nmh} = \frac{10^6}{60n} L_{nm}$$

where

$L_{nm}$  = SKF rating life (at  $100 - n^1$  % reliability) [million revolutions]

$L_{nmh}$  = SKF rating life (at  $100 - n^1$  % reliability) [operating hours]

$L_{10}$  = basic rating life (at 90% reliability) [million revolutions]

$a_1$  = life adjustment factor for reliability (→ **table 1**, values in accordance with ISO 281)

$a_{SKF}$  = SKF life modification factor (→ **diagrams 1 to 4**)

$C$  = basic dynamic load rating [kN]

$P$  = equivalent dynamic bearing load [kN]

$n$  = rotational speed [r/min]

$p$  = exponent of the life equation  
 – for ball bearings,  $p = 3$   
 – for roller bearings,  $p = 10/3$

**Table 2** (→ **page 70**) provides commonly used conversion factors for bearing life in units other than million revolutions.

### SKF life modification factor $a_{SKF}$

This factor represents the relationship between the fatigue load limit ratio ( $P_u/P$ ), the lubrication condition (viscosity ratio  $\kappa$ ) and the contamination level in the bearing ( $\eta_c$ ). Values for the factor  $a_{SKF}$  can be obtained from four diagrams, depending on the bearing type, as a function of  $\eta_c (P_u/P)$  for SKF standard and SKF Explorer bearings and for different values of the viscosity ratio  $\kappa$ . The diagrams are referenced in the following.

- for radial ball bearings (→ **diagram 1, page 66**)
- for radial roller bearings (→ **diagram 2, page 67**)
- for thrust ball bearings (→ **diagram 3, page 68**)
- for thrust roller bearings (→ **diagram 4, page 69**)

The diagrams are drawn for values and safety factors typically associated with fatigue load limits for other mechanical components. Considering the simplifications inherent in the SKF rating life equation, even if the operating conditions are accurately identified, it is not meaningful to use values of  $a_{SKF}$  in excess of 50.

**Table 1**

#### Values for life adjustment factor $a_1$

## Selecting bearing size

### Calculating the life modification factor $a_{SKF}$

SKF engineering programs like *SKF Bearing Select*, available online at [skf.com/bearingselect](http://skf.com/bearingselect) can be used to calculate the factor  $a_{SKF}$ . Furthermore, SKF has also developed sophisticated computer programs incorporating the SKF rating life equation directly at the rolling contact stress level, permitting other factors influencing bearing life, such as misalignment, shaft deflection and housing deformation, to be taken into account (→ *SKF calculation tools*, page 92).

## Lubrication conditions – the viscosity ratio $\kappa$

The effectiveness of a lubricant is primarily determined by the degree of surface separation between the rolling contact surfaces. If an adequate lubricant film is to be formed, the lubricant must have a given minimum viscosity when the application has reached its operating temperature. The condition of the lubricant is described by the viscosity ratio  $\kappa$  as the ratio of the actual viscosity  $\nu$  to the rated viscosity  $\nu_1$  for adequate lubrication, when the lubricant is at normal operating temperature (→ *Selecting lubricating oils*, page 266). It follows from using

$$\kappa = \frac{\nu}{\nu_1}$$

where

$\kappa$  = viscosity ratio

$\nu$  = actual operating viscosity of the lubricant [mm<sup>2</sup>/s]

$\nu_1$  = rated viscosity of the lubricant depending on the bearing mean diameter and rotational speed [mm<sup>2</sup>/s]

The rated viscosity  $\nu_1$ , required for adequate lubrication (→ *Viscosity ratio  $\kappa$* , page 241), can be determined from **diagram 5** (→ page 72), using the bearing mean diameter  $d_m = 0,5 (d + D)$  [mm] and the rotational speed of the bearing  $n$  [r/min]. This diagram takes the latest findings of tribology in rolling bearings into account.

When the operating temperature is known from experience or can otherwise be determined, the corresponding viscosity at the internationally standardized reference temperature of 40 °C (105 °F) can be obtained from **diagram 6** (→ page 73), or can be calculated. The diagram is compiled for a viscosity index of 95. **Table 3** lists the viscosity grades in accordance with ISO 3448 showing the viscosity range for each grade at 40 °C (105 °F). Certain bearing types like spherical roller bearings, tapered roller bearings and spherical roller thrust bearings, normally have a higher operating temperature than other bearing types, such as deep groove ball bearings and cylindrical roller bearings, under comparable operating conditions.

## Selecting bearing size

### Calculation example

A bearing with a bore diameter  $d = 340$  mm and an outside diameter  $D = 420$  mm is required to operate at a speed  $n = 500$  r/min. Since  $d_m = 0,5 (d + D) = 380$  mm, from **diagram 5**, the minimum rated viscosity  $\nu_1$  required to provide adequate lubrication at the operating temperature is approximately  $11$  mm<sup>2</sup>/s. From **diagram 6**, assuming that the operating temperature of the bearing is  $70$  °C ( $160$  °F), a lubricant in the ISO VG 32

viscosity class, with an actual viscosity  $\nu$  of at least  $32$  mm<sup>2</sup>/s at the reference temperature of  $40$  °C ( $105$  °F), is required.

Diagram 5

### Estimation of the minimum kinematic viscosity $\nu_1$ at operating temperature

### Considering EP additives

EP additives in the lubricant can extend bearing service life when, in accordance with ISO 281,  $\kappa < 1$  and the factor for the contamination level  $\eta_c \geq 0,2$ . Under these conditions, a value of  $\kappa = 1$  can be applied in the calculation of  $a_{SKF}$ , if a proven lubricant with effective EP additives is used. In this case, the life modification factor has to be limited to  $a_{SKF} \leq 3$ , but should never be lower than  $a_{SKF}$  for normal lubricants.

For the remaining range, the life modification factor  $a_{SKF}$  can be determined using the actual  $\kappa$  of the application. In case of severe contamination, i.e. contamination factor  $\eta_c < 0,2$ , the possible benefit of an EP additive should be proven by testing. Refer to the information about EP additives under *Lubrication* (→ page 239).

## Selecting bearing size

### Factor $\eta_c$ for contamination level

This factor was introduced to consider the contamination level of the lubricant in the bearing life calculation. The influence of contamination on bearing fatigue depends on a number of parameters including bearing size, relative lubricant film thickness, size and distribution of solid contaminant particles and types of contaminants (soft, hard etc.). The influence of these parameters on bearing life is complex and many of the parameters are difficult to quantify. It is therefore not possible to allocate precise values to  $\eta_c$  that would have general validity. However, some guideline values in accordance with ISO 281 are listed in **table 4**.

### ISO contamination classification and filter rating

The standard method for classifying the contamination level in a lubrication system is described in ISO 4406. In this classification system, the result of the solid particle count is converted into a code using a scale number (→ **table 5** and **diagram 7, pages 75 and 78**).

One method to check the contamination level of bearing oil is the microscope counting method. This method uses two particle size ranges:  $\geq 5 \mu\text{m}$  and  $\geq 15 \mu\text{m}$ . Another more modern method is to use an optical automatic particle counter in accordance with ISO 11171. The calibration scale of the automatic counting method differs from that of the microscopic counting method. It uses three particle size ranges indicated by the symbol (c) e.g.  $\geq 4 \mu\text{m}(c)$ ,

<b>Very severe contamination</b> <ul style="list-style-type: none"> <li>typical conditions: contamination levels so severe that values of <math>\eta_c</math> are outside the scale, which significantly reduces the bearing life</li> </ul>	0	0

<sup>1)</sup> The scale for  $\eta_c$  refers only to typical solid contaminants. Contaminants like water or other fluids detrimental to bearing life is not included. Due to strong abrasive wear in highly contaminated environments ( $\eta_c = 0$ ) the useful life of a bearing can be significantly shorter than the rated life.

$\geq 6 \mu\text{m}(c)$  and  $\geq 14 \mu\text{m}(c)$ . Typically, only the two larger particle size ranges are used, as the larger particles have a more significant impact on bearing fatigue.

Typical examples of contamination level classifications for lubricating oils are -/15/12 (A) or 22/18/13 (B), as shown in **diagram 7** (→ **page 78**).

Example A indicates that the oil contains between 160 and 320 particles  $\geq 5 \mu\text{m}$  and between 20 and 40 particles  $\geq 15 \mu\text{m}$  per millilitre of oil. Though it would be optimal if lubricating oils were continuously filtered, the viability of a filtration system would depend on the equipment costs versus maintenance and downtime costs.

A filter rating is an indication of filter efficiency and is expressed as a reduction factor ( $\beta$ ). The higher the  $\beta$  value, the more efficient the filter is for the specified particle size. The filter rating  $\beta$  is expressed as a ratio between the number of specified particles before and after filtering. This can be calculated using

$$\beta_{x(c)} = \frac{n_1}{n_2}$$

where

- $\beta_{x(c)}$  = filter rating related to a specified particle size  $x$
- $x$  = particle size ( $c$ ) [ $\mu\text{m}$ ] based on the automatic particle counting method, calibrated in accordance with ISO 11171
- $n_1$  = number of particles per volume unit larger than  $x$ , upstream the filter
- $n_2$  = number of particles per volume unit larger than  $x$ , downstream the filter

**NOTE:** The filter rating  $\beta$  only relates to one particle size in  $\mu\text{m}$ , which is shown in the index such as  $\beta_{3(c)}$ ,  $\beta_{6(c)}$ ,  $\beta_{12(c)}$ , etc. For example, a complete rating " $\beta_{6(c)} = 75$ " means that only 1 in 75 particles,  $6 \mu\text{m}$  or larger passes through the filter.

## Selecting bearing size

### Determining $\eta_c$ when the contamination level is known

Once the oil contamination level is known, either from the microscope counting method or the automatic particle counting method, both in accordance with ISO 4406, or indirectly as a result of the filtration ratio that is applied in an oil circulation system, this information can be used to determine the factor  $\eta_c$ . Note that the factor  $\eta_c$  cannot be derived solely from a particle count. It depends largely on the lubrication conditions, such as  $\kappa$ , and the size of the bearing. A simplified method in accordance with ISO 281 is presented here to obtain the  $\eta_c$  factor for a given application. From the oil contamination code (or filtration ratio of the application), the contamination factor  $\eta_c$  is obtained, using the bearing mean diameter  $d_m = 0,5 (d + D)$  [mm] and the viscosity ratio  $\kappa$  for that bearing (→ **diagrams 8 and 9, page 79**).

**Diagrams 8 and 9** provide typical values for the factor  $\eta_c$  for circulating oil lubrication systems with different degrees of oil filtration and oil contamination codes. Similar contamination factors can be applied in applications where an oil bath shows virtually no increase in the contamination particles present in the system. On the other hand, if the number of particles in an oil bath continues to increase over time, due to excessive wear or the ingress of contaminants, this must be reflected in the choice of the factor  $\eta_c$  used for the oil bath system as indicated in ISO 281.

For grease lubrication,  $\eta_c$  can be determined in a similar way using ISO values for five levels of contamination as shown in **table 6**.

**Diagrams 10 and 11 (→ page 80)**, provide typical values for the factor  $\eta_c$  for grease lubrication for high and normal cleanliness (→ **table 6**).

<sup>1)</sup> When  $d_m \geq 500$  mm, use 1,677

For other degrees of contamination or in the most general case of circulating oil, oil bath and grease lubrication, the contamination factor for a bearing arrangement can be determined using the simplified equation

$$\eta_c = \min(c_1 \kappa^{0,68} d_m^{0,55}, 1) \left[ 1 - \left( \frac{c_2}{3\sqrt{d_m}} \right) \right]$$

min (#1, #2) = use the smallest of the two values

where  $c_1$  and  $c_2$  are constants characterizing the cleanliness of the oil in accordance with ISO 4406, or of the grease according to the classifications in **table 6**. Note that in case of oil filtration, the corresponding level of filtration efficiency (in accordance with ISO 16689) (→ **table 7**) can also be applied in place of the metrological characterization of the status of cleanliness of the oil.

### Calculating life with variable operating conditions

In some applications, like industrial gearboxes, the operating conditions, such as the magnitude and direction of loads, speeds, temperatures and lubrication conditions are continually changing. In these types of applications, bearing life cannot be calculated without first reducing the load spectrum or duty cycle of the application to a limited number of simpler load cases (→ **diagram 12**). In case of continuously changing load, each different load level can be accumulated and the load spectrum reduced to a histogram of constant load blocks. Each block should characterize a given percentage or time-fraction during operation. Note that heavy and normal loads consume bearing life at a faster rate than light loads. Therefore, it is important to have shock and peak loads well represented in the load diagram, even if the occurrence of these loads is relatively rare and limited to a few revolutions.

Within each duty interval, the bearing load and operating conditions can be averaged to some constant value. The number of operating hours or revolutions expected from each duty interval showing the life fraction required by that particular load condition should also be included. Therefore, if  $N_1$  equals the number of revolutions required under the load condition  $P_1$ , and  $N$  is the expected number of revolutions for the completion of all variable loading cycles, then the cycle fraction  $U_1 = N_1/N$  is used by the load condition  $P_1$ , which has a calculated life of  $L_{10m1}$ . Under variable operating conditions, bearing life can be rated using

$$L_{10m} = \frac{1}{\frac{U_1}{L_{10m1}} + \frac{U_2}{L_{10m2}} + \frac{U_3}{L_{10m3}} + \dots}$$

where  
 $L_{10m}$  = SKF rating life (at 90% reliability) [million revolutions]  
 $L_{10m1}, L_{10m2}, \dots$  = SKF rating lives (at 90% reliability) under constant conditions 1, 2, ... [million revolutions]  
 $U_1, U_2, \dots$  = life cycle fraction under the conditions 1, 2, ...  
 Note:  $U_1 + U_2 + \dots U_n = 1$

The use of this calculation method depends very much on the availability of representative load diagrams for the application. Note that this type of load history can also be derived from a similar type of application.

Diagram 12

## Selecting bearing size

### Influence of the operating temperature

In operation, the dimensions of a bearing change as a result of structural transformations within the material. These transformations are influenced by temperature, time and stress.

To avoid inadmissible dimensional changes as a result of structural transformation, bearing components undergo a special heat treatment (→ **table 8**).

Depending on the bearing type, standard bearings made of steels for through-hardening or induction-hardening have a recommended maximum operating temperature between 120 and 200 °C (250 and 390 °F). These maximum operating temperatures are directly related to the heat treatment that was applied. For additional information, refer to the introductory text of the relevant product chapter. If the normal operating temperatures of the application are higher than the recommended temperature limit, a bearing with a higher stabilization class should be considered. For applications where bearings operate continuously at elevated temperatures, the dynamic load carrying capacity of the bearing may need to be adjusted in the life calculations. For additional information, contact the SKF application engineering service.

The satisfactory operation of bearings at elevated temperatures also depends on whether the lubricant retains its lubricating properties and whether the materials used for the seals, cages etc. are suitable (→ *Lubrication*, **page 239**, and *Materials for rolling bearings*, **page 150**).

For bearings operating at high temperatures requiring a higher stabilization class than S1, contact the SKF application engineering service.

### Requisite rating life

When determining bearing size, verify the calculated SKF rating life with the specification life of the application, if it is available. This usually depends on the type of machine and the requirements regarding duration of service and operational reliability. In the absence of previous experience, the guideline values listed in **tables 9** and **10** can be used.

# Dynamic bearing loads

## Calculating dynamic bearing loads

The loads acting on a bearing can be calculated according to the laws of mechanics if the external forces, such as forces from power transmission, work forces or inertial forces, are known or can be calculated. When calculating the load components for a single bearing, the shaft is considered as a beam resting on rigid, moment-free supports for the sake of simplification. Elastic deformations in the bearing, the housing or the machine frame are not considered, nor are the moments produced in the bearing as a result of shaft deflection.

These simplifications are necessary if a bearing arrangement is to be calculated without a computer program. The standardized methods for calculating basic load ratings and equivalent bearing loads are based on similar assumptions.

It is possible to calculate bearing loads based on the theory of elasticity, without making the above assumptions, but this requires the use of complex computer programs. In these programs, the bearings, shaft and housing are considered as resilient components of a system.

If external forces and loads like inertial forces or loads resulting from the weight of a shaft and its components are not known, they can be calculated. However, when determining work forces and loads, e.g. rolling forces, moment loads, unbalanced loads and shock loads, it may be necessary to rely on estimates based on experience with similar machines or bearing arrangements.

## Geared transmissions

With geared transmissions, the theoretical tooth forces can be calculated from the power transmitted and the design characteristics of the gear teeth. However, there are additional dynamic forces, produced either by the gear, or by the input or output shaft. Additional dynamic forces from gears can be the result of form errors of the teeth and from unbalanced rotating components. Because of the requirements for quiet running, gears are made to such a high level of accuracy that these forces are generally negligible, and not considered when making bearing calculations.

Additional forces arising from the type and mode of operation of the machines coupled to the transmission can only be determined when the operating conditions are known. Their influence on the rating lives of the bearings is considered using an "operation" factor that takes shock loads and the efficiency of the gears into account. Values of this factor for different operating conditions can usually be found in information published by the gear manufacturer.

## Belt drives

When calculating bearing loads for belt driven applications, "belt pull" must be taken into consideration. Belt pull, which is a circumferential load, depends on the amount of torque being transmitted. The belt pull must be multiplied by a factor, which depends on the type of belt, belt tension and any additional dynamic forces. Belt manufacturers usually publish values. However, should information not be available, the following values can be used:

- toothed belts = 1,1 to 1,3
- V-belts = 1,2 to 2,5
- plain belts = 1,5 to 4,5

The larger values apply when the distance between shafts is short, for heavy or shock-type duty, or where belt tension is high.

## Equivalent dynamic bearing load

The above information can be used to calculate the bearing load  $F$ . When the bearing load fulfills the requirements for the basic dynamic load rating  $C$ , i.e. the load is constant in magnitude and direction and acts radially on a radial bearing or axially and centrally on a thrust bearing, then  $P = F$  and the load may be inserted directly into the life equations.

In all other cases, the equivalent dynamic bearing load must be calculated first. The equivalent dynamic bearing load is defined as that hypothetical load, constant in magnitude and direction, acting radially on a radial bearing or axially and centrally on a thrust bearing which, if applied, would have the same influence on bearing life as the actual loads to which the bearing is subjected (→ **fig. 2**).

Radial bearings are often subjected to simultaneously acting radial and axial loads. If the resultant load is constant in magnitude and direction, the equivalent dynamic bearing load  $P$  can be obtained from the general equation

$$P = X F_r + Y F_a$$

where

$P$  = equivalent dynamic bearing load [kN]

$F_r$  = actual radial bearing load [kN]

$F_a$  = actual axial bearing load [kN]

$X$  = radial load factor for the bearing

$Y$  = axial load factor for the bearing

An additional axial load only influences the equivalent dynamic load  $P$  for a single row

radial bearing if the ratio  $F_a/F_r$  exceeds a certain limiting factor  $e$ . With double row bearings, even light axial loads are generally significant.

The same general equation also applies to spherical roller thrust bearings, which can accommodate both axial and radial loads. Other thrust bearings like thrust ball bearings and cylindrical and needle roller thrust bearings, can accommodate pure axial loads only. For these bearings, provided the load acts centrally, the equation can be simplified to

$$P = F_a$$

Information and data required for calculating the equivalent dynamic bearing load is provided in the relevant product chapter.

## Fluctuating bearing load

In many cases, the magnitude of the load fluctuates. The formula to calculate fluctuating loads can be found under *Calculating life with variable operating conditions* (→ **page 81**).

## Mean load within a duty interval

Within each loading interval the operating conditions can vary slightly from the nominal value. Assuming that the operating conditions like speed and load direction are fairly constant and the magnitude of the load constantly varies between a minimum value  $F_{\min}$  and a maximum value  $F_{\max}$  (→ **diagram 13, page 86**), the mean load can be obtained from

$$F_m = \frac{F_{\min} + 2 F_{\max}}{3}$$

Fig. 2

## Selecting bearing size

Diagram 13

### Load averaging

### Rotating load

If, as illustrated in **diagram 14**, the load on a bearing consists of a load  $F_1$ , which is constant in magnitude and direction, such as the weight of a rotor, and a rotating constant load  $F_2$ , such as an unbalance load, the mean load can be obtained from

$$F_m = f_m (F_1 + F_2)$$

Values for the factor  $f_m$  are provided in **diagram 15**.

### Requisite minimum load

The correlation between load and service life is less important for applications where there are very light loads. Failure mechanisms other than fatigue often prevail.

To provide satisfactory operation, ball and roller bearings must always be subjected to a given minimum load. A general “rule of thumb” indicates that minimum loads corresponding to 0,02 C should be imposed on roller bearings and minimum loads corresponding to 0,01 C on ball bearings. The importance of applying a minimum load increases in applications where there are rapid accelerations or rapid starts and stops, and where speeds exceed 50% of the limiting speeds listed in the product tables (→ *Speeds*, **page 117**). If minimum load requirements cannot be met, NoWear coated bearings should be considered (→ **page 1241**).

Recommendations for calculating the requisite minimum load for different bearing types are provided in the relevant product chapter.

## Selecting bearing size using static load carrying capacity

Bearing size should be selected on the basis of static load ratings  $C_0$  instead of on bearing life when one of the following conditions exist:

- The bearing is stationary and is subjected to continuous or intermittent (shock) loads.
- The bearing makes slow oscillating or alignment movements under load.
- The bearing rotates under load at very slow speed ( $n < 10$  r/min) and is only required to have a short life. In other words, the life equation in this case, for a given equivalent load  $P$ , would give such a low requisite basic dynamic load rating  $C$ , that the bearing selected on a life basis would be seriously overloaded in service.
- The bearing rotates and, in addition to the normal operating loads, has to sustain heavy shock loads.

In all these cases, the permissible load for the bearing is the maximum load the bearing can accommodate without permanent deformation to the rolling elements or raceways. Permanent deformation is typically caused by:

- heavy loads acting on the bearing while it is stationary or oscillating slowly
- heavy shock loads acting on the bearing while it is rotating

Depending on the operating conditions and load, the resulting damage can be flattened areas on the rolling elements or indentations on the raceways. The indentations can be irregularly spaced around the raceway, or may be evenly spaced at positions corresponding to the spacing of the rolling elements.

Permanent deformations usually lead to higher vibration and/or noise levels and increased friction. It is also possible that the internal clearance will increase or the character of the fits may be changed.

The extent to which these changes are detrimental to bearing performance depends on the demands placed on the bearing in a particular application. It is therefore necessary to make sure that permanent deformations do not occur, or only occur to a very limited extent by selecting a bearing with sufficiently high static load carrying capacity, if one of the following demands has to be satisfied:

- high reliability
- quiet running, such as for electric motors
- vibration-free operation, such as for machine tools
- constant bearing frictional moment, such as for measuring apparatus and test equipment
- low starting friction under load, such as for cranes

## Selecting bearing size

### Equivalent static bearing load

Static loads comprising radial and axial components must be converted into an equivalent static bearing load. This is defined as that hypothetical load (radial for a radial bearing and axial for a thrust bearing) which, if applied, would cause the same maximum rolling element load in the bearing as the actual loads to which the bearing is subjected. It is obtained from the general equation

$$P_0 = X_0 F_r + Y_0 F_a$$

where

$P_0$  = equivalent static bearing load [kN]

$F_r$  = actual radial bearing load (see below) [kN]

$F_a$  = actual axial bearing load (see below) [kN]

$X_0$  = radial load factor for the bearing

$Y_0$  = axial load factor for the bearing

Information and data required for calculating the equivalent static bearing load is provided in the relevant product chapter.

When calculating  $P_0$ , the maximum load that can occur should be used and its radial and axial components (→ **fig. 3**) inserted in the equation above. If a static load acts in different directions on a bearing, the magnitude of these components changes. In these cases, the components of the load with the highest value of the equivalent static bearing load  $P_0$  should be used.

### Required basic static load rating

When determining bearing size based on the static load carrying capacity, a given safety factor  $s_0$ , which represents the relationship between the basic static load rating  $C_0$  and the equivalent static bearing load  $P_0$ , is used to calculate the requisite basic static load rating.

The required basic static load rating  $C_0$  can be determined from

$$C_0 = s_0 P_0$$

where

$C_0$  = basic static load rating [kN]

$P_0$  = equivalent static bearing load [kN]

$s_0$  = static safety factor

Guideline values for the static safety factor  $s_0$  based on experience are listed in **table 11**. At elevated temperatures, the static load carrying capacity is reduced. For additional information, contact the SKF application engineering service.

Fig. 3

### Checking the static load carrying capacity

For dynamically loaded bearings, where the equivalent static bearing load  $P_0$  is known, it is advisable to check that the static load carrying capacity is adequate using

$$s_0 = \frac{C_0}{P_0}$$

If the  $s_0$  value obtained is less than the recommended guideline value (→ **table 11**), a bearing with a higher basic static load rating should be selected.

B

Table 11

**Guideline values for the static safety factor  $s_0$**

Type of operation	Rotating bearing						Non-rotating bearing	
	Performance requirements (e.g. quiet running or vibration-free operation)							
	unimportant		normal		high			
	Ball bearings	Roller bearings	Ball bearings	Roller bearings	Ball bearings	Roller bearings	Ball bearings	Roller bearings
<b>Smooth, vibration-free</b>	0,5	1	1	1,5	2	3	0,4	0,8

<b>Pronounced shock loads<sup>1)</sup></b>	≥ 1,5	≥ 2,5	≥ 1,5	≥ 3	≥ 2	≥ 4	≥ 1	≥ 2

For spherical roller thrust bearings, it is advisable to use  $s_0 \geq 4$ .

<sup>1)</sup> Where the magnitude of the shock load is not known, values of  $s_0$  at least as large as those quoted above should be used. If the magnitude of the shock loads is known, smaller values of  $s_0$  can be applied.

## Calculation examples

### Example 1: Basic rating life and SKF rating life

An SKF Explorer 6309 deep groove ball bearing is to operate at 3 000 r/min under a constant radial load  $F_r = 10$  kN. Oil lubrication is to be used, the oil has an actual kinematic viscosity  $\nu = 20$  mm<sup>2</sup>/s at normal operating temperature. The desired reliability is 90% and it is assumed that the operating conditions are very clean. What are the basic and SKF rating lives?

a) The basic rating life for 90% reliability is

$$L_{10} = \left( \frac{C}{P} \right)^3$$

From the product table for bearing 6309,  $C = 55,3$  kN. Since the load is purely radial,  $P = F_r = 10$  kN (→ *Equivalent dynamic bearing load*, page 85).

$$L_{10} = \left( \frac{55,3}{10} \right)^3$$

= 169 million revolutions

or in operating hours, using

$$L_{10h} = \frac{10^6}{60 \text{ n}} L_{10}$$

$$L_{10h} = \frac{1\,000\,000}{60 \times 3\,000} \times 169$$

= 940 operating hours

b) The SKF rating life for 90% reliability is

$$L_{10m} = a_1 a_{SKF} L_{10}$$

- As a reliability of 90% is required, the  $L_{10m}$  life is to be calculated and  $a_1 = 1$  (→ **table 1**, page 65).
- From the product table for bearing 6309,  $d_m = 0,5$  ( $d + D$ ) =  $0,5$  ( $45 + 100$ ) =  $72,5$  mm

- From **diagram 5** (→ **page 72**), the rated oil viscosity at operating temperature for a speed of 3 000 r/min,  $\nu_1 = 8,15$  mm<sup>2</sup>/s. Therefore,  $\kappa = \nu/\nu_1 = 20/8,15 = 2,45$
- From the product table  $P_u = 1,34$  kN and  $P_u/P = 1,34/10 = 0,134$ . As the conditions are very clean,  $\eta_c = 0,8$  (→ **table 4**, page 74) and  $\eta_c (P_u/P) = 0,107$ . With  $\kappa = 2,45$  and using the SKF Explorer scale in **diagram 1** (→ **page 66**), the value of  $a_{SKF} = 8$  is obtained. Then, according to the SKF rating life equation

$$\begin{aligned} L_{10m} &= 1 \times 8 \times 169 \\ &= 1\,352 \text{ million revolutions} \end{aligned}$$

or in operating hours using

$$L_{10mh} = \frac{10^6}{60 \text{ n}} L_{10m}$$

$$L_{10mh} = \frac{1\,000\,000}{60 \times 3\,000} \times 1\,352$$

= 7 512 operating hours

### Example 2: Check contamination conditions

An existing application has to be reviewed.

An SKF Explorer 6309-2RS1 deep groove ball bearing with integral seals and standard grease fill is working under the same conditions as described in example 1 ( $\kappa = 2,45$ ). The contamination conditions of this application have to be checked to determine if it is possible to use a more cost-effective bearing for a minimum requisite life of 3 000 hours of operation.

- Considering grease lubrication and integral seals, the level of contamination can be characterized as high cleanliness and from **table 4** (→ **page 74**),  $\eta_c = 0,8$ . With  $P_u/P = 0,134$ ,  $\eta_c (P_u/P) = 0,107$ , using the SKF Explorer scale in **diagram 1** (→ **page 66**) and  $\kappa = 2,45$ ,  $a_{SKF} = 8$ .

$$L_{10mh} = 8 \times 940 = 7\,520 \text{ operating hours}$$

- A more cost-effective bearing arrangement would use a shielded SKF Explorer 6309-2Z bearing. The contamination level can be characterized as normal cleanliness, then from **table 4** (→ **page 74**)  $\eta_c = 0,5$ . With  $P_u/P = 0,134$ ,  $\eta_c (P_u/P) = 0,067$ , using the SKF Explorer scale in **diagram 1** (→ **page 66**) and  $\kappa = 2,45$ ,  $a_{SKF} \approx 3,5$ .

$L_{10mh} = 3,5 \times 940 = 3\ 290$  operating hours

Conclusion: This application would be able to take advantage of a more cost-effective solution by replacing the sealed bearing with a shielded bearing.

**Example 3: Verify dynamic and static load conditions**

The duty cycle of a sealed SKF Explorer spherical roller bearing 24026-2CS2/VT143 used in heavy transportation equipment of a steel plant has the operating conditions listed in the table below.

The static load of this application is determined with reasonable accuracy by taking into account the inertial loads that occur during loading and the shock loads that can occur if something is accidentally dropped.

It is required to verify the dynamic and static load conditions of this application, assuming a required  $L_{10mh}$  operating life of 60 000 hours and a minimum static safety factor of 1,5.

- From the product table and introductory text:

Load ratings:  
 $C = 540$  kN;  $C_0 = 815$  kN;  $P_u = 81,5$  kN

Dimensions:  
 $d = 130$  mm;  $D = 200$  mm,  
 therefore,  $d_m = 0,5 (130 + 200) = 165$  mm

Grease fill  
 Extreme pressure grease with a lithium thickener and mineral base oil, of NLGI consistency class 2, for a temperature range of  $-20$  to  $+110$  °C ( $-5$  to  $+230$  °F) and a base oil viscosity at 40 and 100 °C ( $105$  and  $210$  °F) of 200 and 16 mm<sup>2</sup>/s, respectively.

- The following calculations are made or values determined:

1  $v_1 =$  rated viscosity, mm<sup>2</sup>/s  
 (→ **diagram 5, page 72**) – input:  $d_m$  and speed

2  $v =$  actual operating viscosity, mm<sup>2</sup>/s  
 (→ **diagram 6, page 73**) – input: lubricant viscosity at 40 °C ( $105$  °F) and operating temperature

3  $\kappa =$  viscosity ratio – calculated ( $v/v_1$ )

4  $\eta_c =$  factor for contamination level  
 (→ **table 4, page 74**) – “High cleanliness”, sealed bearing:  $\eta_c = 0,8$

Example 3/1

Operating conditions

–	kN	–	r/min	°C	°F	kN
1	200	0,05	50	50	120	500
2	125	0,40	300	65	150	500
3	75	0,45	400	65	150	500
4	50	0,10	200	60	140	500

## Selecting bearing size

- 5  $L_{10h}$  = basic rating life according to the equation (→ **page 64**) – input: C, P and n
- 6  $a_{SKF}$  = from **diagram 2** (→ **page 67**) – input: SKF Explorer bearing,  $\eta_c$ ,  $P_u$ , P and  $\kappa$
- 7  $L_{10mh1,2, \dots}$  = SKF rating life according to the equation (→ **page 65**) – input:  $a_{SKF}$  and  $L_{10h1,2, \dots}$
- 8  $L_{10mh}$  = SKF rating life according to the equation (→ **page 81**) – input:  $L_{10mh1}$ ,  $L_{10mh2}$ , ... and  $U_1$ ,  $U_2$ , ...

The SKF rating life of 84 300 hours exceeds the required operating life, therefore, the dynamic load conditions of the bearing are verified.

Finally, the static safety factor of this application is verified using

$$s_0 = \frac{C_0}{P_0} = \frac{815}{500} = 1,63$$

$$s_0 = 1,63 > s_{0 \text{ req}}$$

The above shows that the static safety of this application is verified. As the static load is determined accurately, the relatively small margin between the calculated and recommended static safety is of no concern.

## SKF calculation tools

SKF possesses one of the most comprehensive and powerful sets of modelling and simulation packages in the bearing industry. They range from easy-to-use tools based on SKF catalogue *Rolling bearings* formulae to the most sophisticated calculation and simulation systems, running on parallel computers.

SKF has developed a range of programs to satisfy a number of customer requirements; from fairly simple design checks, through moderately complex investigations, to the most advanced simulations for bearing and machine design. Wherever possible, these programs are available for customers to use on their computers. Moreover, particular care is taken to provide integration and interoperability of the different systems with each other.

### Calculation tools available online at [skf.com/bearingcalculator](http://skf.com/bearingcalculator)

Easy-to-use tools for bearing selection and calculation are available online at [skf.com/bearingcalculator](http://skf.com/bearingcalculator). Bearing searches are available based on designation or dimensions, and simple bearing arrangements can be evaluated as well. The equations used are consistent with those used in this catalogue.

SKF's interactive engineering tools make it possible to generate drawings of bearings and housings that can be used in most commercially available CAD programs.

## SKF bearing beacon

SKF bearing beacon is the mainstream bearing application program used by SKF engineers to find the best solution for customers' bearing systems. Working in a virtual environment, SKF engineers combine mechanical systems containing shafts, gears and housings with a precise bearing model for an in-depth analysis of the system's behaviour. The program can also analyze rolling fatigue in a bearing using the SKF rating life method. SKF bearing beacon is the result of years of research and development within SKF.

## Orpheus

The numerical tool Orpheus is used to study and optimize the dynamic behaviour of noise and vibration-critical bearing applications, such as electric motors, gearboxes. The program is also used to solve complete non-linear equations of motion for a bearing arrangement and the surrounding components, such as gears, shafts and housings.

Orpheus can provide a profound understanding of the dynamic behaviour of an application, including the bearings, accounting for form deviations (waviness) and misalignment. This enables SKF engineers to determine the most suitable bearing type and size as well as the corresponding mounting and preload conditions for a given application.

## Beast

Beast is a simulation program that enables SKF engineers to simulate the detailed dynamics inside a bearing. It can be seen as a virtual test rig performing detailed studies of forces, moments etc. inside a bearing under virtually any load condition. This enables the "testing" of new concepts and designs in a shorter time and with more information gained compared with traditional physical testing.

## Other programs

In addition to the above-mentioned programs, SKF has developed dedicated computer programs that enable SKF scientists to provide customers with bearings having an optimized bearing surface finish to extend bearing service life under severe operating conditions. These programs can calculate the lubricant film thickness in elasto-hydrodynamically lubricated contacts. In addition, the local film thickness resulting from the deformation of the three dimensional surface topography inside such contacts is calculated in detail and the consequent reduction of bearing fatigue life.

SKF engineers also use commercial packages to perform, for example, finite element or generic system dynamics analyses. These tools are integrated with the SKF proprietary systems enabling a faster and more robust connection with customer data and models.

### SKF Engineering Consultancy Services

The basic information required to calculate and design a bearing arrangement can be found in this catalogue. But there are applications where it is desirable to predict the expected bearing life as accurately as possible, either because sufficient experience with similar bearing arrangements is lacking, or because economy and/or operational reliability are of extreme importance. In these cases, for example, it is advisable to consult SKF Engineering Consultancy Services. They provide calculations and simulations utilizing high-tech computer programs, in combination with one hundred years of accumulated experience in the field of rotating machine components.

They can provide support with the complete SKF application know-how. The SKF application engineering specialists can support with the following services:

- analyse technical problems
- suggest appropriate system solutions
- select the appropriate lubricant and lubrication method and an optimized maintenance programme

SKF Engineering Consultancy Services provides a new approach to services concerning machines and installations for OEMs and end-users. Some of these service benefits are:

- faster development processes and reduced time to market
- reduced implementation costs by virtual testing before production starts
- improved bearing arrangement by reducing noise and vibration levels
- higher power density by upgrading
- extended service life by improving the lubrication or sealing system

### Advanced computer programs

Within the SKF Engineering Consultancy Services, there are highly advanced computer programs which can be used for the following:

- analytical modelling of complete bearing arrangements, consisting of shaft, housing, gears, couplings, etc.
- static analysis to determine the elastic deformations and stresses in components of mechanical systems
- dynamic analysis to determine the vibration behaviour of systems under working conditions ("virtual testing")
- visual and animated presentation of structural and component deflection
- optimizing system costs, service life, vibration and noise levels

The standard computer programs used within the SKF Engineering Consultancy Services for calculations and simulations are described briefly under *SKF calculation tools* (→ **page 92**).

## SKF life testing

SKF endurance testing activities are concentrated at the SKF Engineering Research Centre in the Netherlands. The test facilities are unique in the bearing industry with regard to sophistication and the number of test rigs and are ISO 17025 accredited. The centre also supports work carried out at the research facilities of the major SKF manufacturing facilities.

SKF undertakes life testing, mainly to be able to continuously improve the design, the materials and the manufacturing processes of bearing products. Furthermore it is also essential to develop and continuously improve the engineering models required for the design of bearing applications.

Typical endurance testing activities include tests on bearing population samples under:

- full-film lubrication conditions
- reduced lubricant film conditions
- predefined contamination conditions of the lubricant

SKF also undertakes life tests to:

- verify the performance commitments made in product catalogues
- audit the quality of the SKF standard bearing production
- research the influences of lubricants and lubricating conditions on bearing life
- support the development of theories for rolling contact fatigue
- compare with competitive products

The powerful and firmly controlled life tests combined with post-test investigations with state-of-the-art equipment make it possible to investigate the factors that affect the life of the bearings in a systematic way.

High performance SKF Explorer and SKF Energy Efficient (E2) bearings are examples of the implementation of the optimized influencing factors on the basis of analytical simulation models and experimental verification at the component and complete bearing level.

## Friction

The friction in a rolling bearing determines the amount of heat generated by the bearing. The amount of friction depends on the loads and several other factors, including:

- bearing type and size
- operating speed
- properties and quantity of the lubricant

The total resistance to rotation in a bearing is the result of rolling and sliding friction in the contact areas, between the rolling elements and raceways, between the rolling elements and cage, and between the rolling elements and other guiding surfaces. Friction is also generated by lubricant drag and contact seals, if applicable.

## Estimating the frictional moment

Under certain conditions, the frictional moment can be estimated with sufficient accuracy using a constant coefficient of friction  $\mu$ . The conditions are:

- bearing load  $P \approx 0,1 C$
- good lubrication
- normal operating conditions

The frictional moment under these conditions can be estimated using

$$M = 0,5 \mu P d$$

For radial needle roller bearings, use  $F$  or  $F_w$  instead of  $d$ .

where

$M$  = frictional moment [Nmm]

$\mu$  = constant coefficient of friction for the bearing (→ **table 1**)

$P$  = equivalent dynamic bearing load [N]

$d$  = bearing bore diameter [mm]

$F$  = inner ring raceway diameter [mm]

$F_w$  = diameter under the rollers [mm]

## The SKF model for calculating the frictional moment

A sketch of the frictional moment in a typical bearing, as a function of rotational speed or viscosity, is presented in **diagram 1**. During the start-up period (zone 1), as speed or viscosity increases, the frictional moment decreases as a hydrodynamic (lubricant) film is being formed. As speeds or viscosity continue to increase and the bearing enters into the full elasto-hydrodynamic lubrication (EHL) zone, the thickness of the hydrodynamic film increases (increasing  $\kappa$  value, **page 241**), which also increases friction (zone 2). Eventually, speed or viscosity increase to the point where kinematic starvation and inlet shear cause friction to reach a plateau or even decrease (zone 3).

For additional information, refer to *Inlet shear heating reduction factor* (→ **page 101**) and *Kinematic replenishment/starvation reduction factor* (→ **page 102**).

To accurately calculate the total frictional moment in a rolling bearing, the following sources and their tribological effects must be taken into account:

- the rolling frictional moment and eventual effects of high-speed starvation and inlet shear heating
- the sliding frictional moment and its effect on the quality of the lubrication
- the frictional moment from seal(s)
- the frictional moment from drag losses, churning, splashing etc.

The SKF model for calculating the frictional moment closely follows the real behaviour of the bearing as it considers all contact areas, design changes and improvements made to SKF bearings as well as internal and external influences.

Diagram 1

Bearing frictional moment as a function of speed or viscosity

## Friction

The SKF model for calculating the frictional moment uses

$$M = M_{rr} + M_{sl} + M_{seal} + M_{drag}$$

where

$M$  = total frictional moment

$M_{rr}$  = rolling frictional moment

$M_{sl}$  = sliding frictional moment (→ page 103)

$M_{seal}$  = frictional moment of seals (→ page 109)

$M_{drag}$  = frictional moment of drag losses, churning, splashing etc. (→ page 110)

The SKF model is derived from more advanced computational models developed by SKF. It is designed to provide approximate reference values under the following application conditions:

- grease lubrication:
  - only steady state conditions (after several hours of operation)
  - lithium soap grease with mineral oil
  - bearing free volume filled approximately 30%
  - ambient temperature 20 °C (70 °F) or higher
- oil lubrication:
  - oil bath, oil-air or oil jet
  - viscosity range from 2 to 500 mm<sup>2</sup>/s
- loads equal to or larger than the recommended minimum load and at least:
  - 0,01 C for ball bearings
  - 0,02 C for roller bearings
- constant loads in magnitude and direction
- normal operating clearance
- constant speed but not higher than the permissible speed

For paired bearings, the frictional moment can be calculated separately for each bearing and added together. The radial load is divided equally over the two bearings; the axial load is shared according to the bearing arrangement.

## Rolling frictional moment

The rolling frictional moment can be calculated using

$$M_{rr} = \phi_{ish} \phi_{rs} G_{rr} (v n)^{0,6}$$

where

$M_{rr}$  = rolling frictional moment [Nmm]

$\phi_{ish}$  = inlet shear heating reduction factor

$\phi_{rs}$  = kinematic replenishment/starvation reduction factor (→ page 102)

$G_{rr}$  = variable (→ table 2, page 104), depending on:

- the bearing type
- the bearing mean diameter  $d_m$  [mm]  
= 0,5 (d + D)
- the radial load  $F_r$  [N]
- the axial load  $F_a$  [N]

$n$  = rotational speed [r/min]

$v$  = kinematic viscosity at operating temperature of the oil or the base oil viscosity of the grease [mm<sup>2</sup>/s]

**NOTE:** The formulae provided in this section lead to rather complex calculations. Therefore, SKF strongly recommends calculating the frictional moment using the tools available online at [skf.com/bearingcalculator](http://skf.com/bearingcalculator).

### Inlet shear heating reduction factor

Compared with the quantity of lubricant available in the bearing, not all of it can go through the contact area. Only a tiny amount of lubricant is used to form a hydrodynamic film. Therefore, some of the oil close to the contact area inlet is rejected and produces a reverse flow (→ **fig. 1**). This reverse flow shears the lubricant, generating heat, which lowers the oil viscosity and reduces the film thickness and rolling friction.

For the effect described above, the inlet shear heating reduction factor can be estimated using

$$\Phi_{ish} = \frac{1}{1 + 1,84 \times 10^{-9} (n d_m)^{1,28} v^{0,64}}$$

where

$\Phi_{ish}$  = inlet shear heating reduction factor  
(→ **diagram 2**)

$n$  = rotational speed [r/min]

$d_m$  = bearing mean diameter [mm]  
= 0,5 (d + D)

$v$  = kinematic viscosity at operating temperature of the oil or the base oil viscosity of the grease [mm<sup>2</sup>/s]

Diagram 2

Inlet shear heating reduction factor  $\Phi_{ish}$

## Friction

### Kinematic replenishment/starvation reduction factor

For oil-air, oil jet, low level oil bath lubrication (i.e. oil level  $H$  lower than the centre of the lowest rolling element) and grease lubrication methods, continuous over-rolling displaces excess lubricant from the raceways. In applications where viscosity or speeds are high, the lubricant may not have sufficient time to replenish the raceways, causing a “kinematic starvation” effect. Kinematic starvation reduces the thickness of the hydrodynamic film (decreasing  $\kappa$  value, **page 241**) and rolling friction.

For the type of lubrication methods described above, the kinematic replenishment/starvation reduction factor can be estimated using

$$\Phi_{rs} = \frac{1}{e^{\left[ K_{rs} \cdot v \cdot n \cdot (d + D) \cdot \sqrt{\frac{K_z}{2(D-d)}} \right]}}$$

where

$\Phi_{rs}$  = kinematic replenishment/starvation reduction factor

$e$  = base of natural logarithm  $\approx 2,718$

$K_{rs}$  = replenishment/starvation constant:

- for low level oil bath and oil jet lubrication  $\rightarrow 3 \times 10^{-8}$
- for grease and oil-air lubrication  $\rightarrow 6 \times 10^{-8}$

$K_z$  = bearing type related geometric constant ( $\rightarrow$  **table 5, page 112**)

$v$  = kinematic viscosity at operating temperature of the oil or the base oil viscosity of the grease [ $\text{mm}^2/\text{s}$ ]

$n$  = rotational speed [r/min]

$d$  = bearing bore diameter [mm]

$D$  = bearing outside diameter [mm]

### Sliding frictional moment

The sliding frictional moment can be calculated using

$$M_{sl} = G_{sl} \mu_{sl}$$

where

$M_{sl}$  = sliding frictional moment [Nmm]

$G_{sl}$  = variable (→ **table 2, page 104**),

depending on:

- the bearing type
- the bearing mean diameter  $d_m$  [mm]  
=  $0,5 (d + D)$
- the radial load  $F_r$  [N]
- the axial load  $F_a$  [N]

$\mu_{sl}$  = sliding friction coefficient

### Effect of lubrication on sliding friction

The sliding friction coefficient for full-film and mixed lubrication conditions can be estimated using

$$\mu_{sl} = \Phi_{bl} \mu_{bl} + (1 - \Phi_{bl}) \mu_{EHL}$$

where

$\mu_{sl}$  = sliding friction coefficient

$\Phi_{bl}$  = weighting factor for the sliding friction coefficient

$$= \frac{1}{e^{2,6 \times 10^{-8} (n v)^{1,4} d_m}}$$

(→ **diagram 3**)

$e$  = base of natural logarithm  $\approx 2,718$

$n$  = rotational speed [r/min]

$v$  = kinematic viscosity at operating temperature of the oil or the base oil viscosity of the grease [mm<sup>2</sup>/s]

$d_m$  = bearing mean diameter [mm]  
=  $0,5 (d + D)$

$\mu_{bl}$  = coefficient depending on the additive package in the lubricant, generally  $\approx 0,15$

$\mu_{EHL}$  = sliding friction coefficient in full-film conditions

Values for  $\mu_{EHL}$  are:

- 0,02 for cylindrical roller bearings
  - 0,002 for tapered roller bearings
- Other bearings
- 0,05 for lubrication with mineral oils
  - 0,04 for lubrication with synthetic oils
  - 0,1 for lubrication with transmission fluids

**Diagram 3** shows the influence of lubrication conditions on the weighting factor for the sliding friction coefficient:

- For full-film lubrication (corresponding to large values of  $\kappa$ , **page 241**), the value of the weighting factor for the sliding friction coefficient  $\Phi_{bl}$  tends to zero.
- For mixed lubrication, which can occur when lubricant viscosity or the bearing speed is low, the value of the weighting factor for the sliding friction coefficient  $\Phi_{bl}$  tends to 1, as occasional metal-to-metal contact may occur and friction increases.

### Frictional moment of seals

Where bearings are fitted with contact seals, the frictional losses from the seals may exceed those generated by the bearing. The frictional moment of seals for bearings that are sealed on both sides can be estimated using

$$M_{\text{seal}} = K_{S1} d_s^\beta + K_{S2}$$

where

$M_{\text{seal}}$  = frictional moment of seals [Nmm]

$K_{S1}$  = constant (→ **table 4**), depending on:

- the seal type
- the bearing type and size

$d_s$  = seal counterface diameter [mm]  
(→ **table 4**)

$\beta$  = exponent (→ **table 4**), depending on:

- the seal type
- the bearing type

$K_{S2}$  = constant (→ **table 4**), depending on:

- the seal type
- the bearing type and size

In cases where there is only one seal, the friction generated is 0,5  $M_{\text{seal}}$ .

For deep groove ball bearings with RSL seals and  $D > 25$  mm, use the calculated value of  $M_{\text{seal}}$ , irrespective whether there is one or two seals.

### Drag losses

Bearings lubricated by the oil bath method are partially submerged or, in special situations, completely submerged. The drag losses that occur when the bearing is rotating in an oil bath contribute to the total frictional moment and should not be neglected. Drag losses are not only influenced by bearing speed, oil viscosity and oil level, but also by the size and geometry of the oil reservoir. External oil agitation, which can originate from mechanical elements, like gears or cams, in close proximity to the bearing should also be taken into consideration.

### Drag losses in oil bath lubrication

The SKF model for calculating the drag losses in oil bath lubrication considers resistance of the rolling elements when moving through the oil and includes the effects of the viscosity of the oil. It provides results with sufficient accuracy under the following conditions:

- The oil reservoir is large. Effects from reservoir size and geometry or external oil agitation are negligible.
- The shaft is horizontal.
- The inner ring rotates at a constant speed. The speed is not higher than the permissible speed.
- The oil viscosity is within the limits:
  - $\leq 500 \text{ mm}^2/\text{s}$  when the bearing is submerged up to half or less (oil level  $H \leq D/2$ )
  - $\leq 250 \text{ mm}^2/\text{s}$  when the bearing is submerged more than half (oil level  $H > D/2$ )

The oil level  $H$  is measured from the lowest contact point between the outer ring raceway and the rolling element (→ **fig. 2, page 112**). It can be estimated with sufficient accuracy using:

- for tapered roller bearings:  
outside diameter  $D$  [mm]
- for all other radial rolling bearings:  
outer ring mean diameter [mm]  
 $= 0,5 (D + D_1)$

The frictional moment of drag losses for ball bearings can be estimated using

$$M_{\text{drag}} = 0,4 V_M K_{\text{ball}} d_m^5 n^2 + 1,093 \times 10^{-7} n^2 d_m^3 \left( \frac{n d_m^2 f_t}{v} \right)^{-1,379} R_s$$

The frictional moment of drag losses for roller bearings can be estimated using

$$M_{\text{drag}} = 4 V_M K_{\text{roll}} C_w B d_m^4 n^2 + 1,093 \times 10^{-7} n^2 d_m^3 \left( \frac{n d_m^2 f_t}{v} \right)^{-1,379} R_s$$

The rolling element related constants are:

$$K_{\text{ball}} = \frac{i_{rw} K_z (d + D)}{D - d} 10^{-12}$$

$$K_{\text{roll}} = \frac{K_L K_z (d + D)}{D - d} 10^{-12}$$

The variables and functions used in the equations for the frictional moment of drag losses are:

$$C_w = 2,789 \times 10^{-10} l_D^3 - 2,786 \times 10^{-4} l_D^2 + 0,0195 l_D + 0,6439$$

$$l_D = 5 \frac{K_L B}{d_m}$$

$$f_t = \begin{cases} \sin(0,5 t), & \text{when } 0 \leq t \leq \pi \\ 1, & \text{when } \pi < t < 2\pi \end{cases}$$

$$R_s = 0,36 d_m^2 (t - \sin t) f_A$$

$$t = 2 \cos^{-1} \left( \frac{0,6 d_m - H}{0,6 d_m} \right) \quad \text{When } H \geq d_m, \text{ use } H = d_m$$

$$f_A = 0,05 \frac{K_z (D + d)}{D - d}$$

where

$M_{\text{drag}}$  = frictional moment of drag losses [Nmm]

$V_M$  = drag loss factor (→ **diagram 4**, **page 112**)

$B$  = bearing width [mm]  
 • for tapered roller bearings → width  $T$   
 • for thrust bearings → height  $H$

$d_m$  = bearing mean diameter [mm]  
 =  $0,5 (d + D)$

$d$  = bearing bore diameter [mm]

$D$  = bearing outside diameter [mm]

$H$  = oil level (→ **fig. 2**, **page 112**) [mm]

$i_{rw}$  = number of ball rows

$K_z$  = bearing type related geometric constant (→ **table 5**, **page 112**)

$K_L$  = rolling bearing type related geometric constant (→ **table 5**, **page 112**)

$n$  = rotational speed [r/min]

$\nu$  = kinematic viscosity at operating temperature [ $\text{mm}^2/\text{s}$ ]

## Friction

### Drag losses for vertical shaft arrangements

To calculate drag losses for vertical shaft arrangements, the model for fully submerged bearings can be used to get an approximate value. The obtained value for  $M_{\text{drag}}$  should be multiplied by a factor equal to the width (height) that is submerged relative to the total bearing width (height).

### Drag losses for oil jet lubrication

To calculate drag losses for the oil jet lubrication method, use the oil bath model, with the oil level  $H$  at half the diameter of the lowest rolling element. The obtained value for  $M_{\text{drag}}$  should be multiplied by a factor of two. Certainly, this approximation can vary depending on the rate and direction of oil. However, if the oil level  $H$  is known when oil is flowing and the bearing is at a stand-still, this value can be used directly in the drag loss calculation to obtain a more accurate estimate.

## Additional effects on the frictional moment

### Effects of clearance and misalignment on friction

Changes in clearance or misalignment in bearings influence the frictional moment. The model above considers normal internal operating clearance and an aligned bearing. However, high bearing operating temperatures or speeds might reduce internal bearing clearance, which can increase friction. Misalignment generally increases friction. However, for self-aligning ball bearings, spherical roller bearings, CARB toroidal roller bearings and spherical roller thrust bearings, the corresponding increase of friction is negligible.

For applications that are sensitive to changes in clearance or misalignment, contact the SKF application engineering service.

### Effects of grease fill on friction

When a bearing has just been lubricated or relubricated with the recommended amount of grease, the bearing can realize considerably higher frictional values than had been calculated originally. It can be seen as an increase in operating temperature. The time it takes for friction to decrease depends on the speed of the application and how long it takes for the grease to distribute itself within the free space in the bearing.

This effect can be estimated by multiplying the rolling frictional moment by a factor of 2 to 4, where 2 applies for light series bearings (narrow width series) and 4 for heavy series bearings.

However, after the running-in period, the values for the frictional moment in the bearing is similar to, or even lower than the values for oil lubricated bearings. Bearings filled with an excessive amount of grease may show higher values of friction. For additional information, refer to *Relubrication* (→ page 252), or contact the SKF application engineering service.

## Additional information for specific bearing types and performance classes

### Hybrid bearings

The higher values for the modulus of elasticity of rolling elements made of silicon nitride decreases the contact area in the raceways to significantly reduce rolling and sliding friction. Additionally, the lower density of ceramic rolling elements, when compared with steel, reduces the centrifugal forces, which also may reduce friction at high speeds.

### Standard hybrid ball bearings

Using the above equations, the frictional moment for hybrid angular contact ball bearings can be calculated by multiplying the geometric constants  $R_3$  and  $S_3$  of the all-steel bearings by a factor 0,41, that is  $0,41 R_3$  and  $0,41 S_3$ , respectively.

Hybrid deep groove ball bearings in high-speed applications are usually preloaded axially. Under these conditions, hybrid deep groove ball bearings behave like angular contact ball bearings with a similar reduced frictional moment. SKF recommends contacting the SKF application engineering service when calculating the frictional moment for hybrid deep groove ball bearings.

### Starting torque

The starting torque of a rolling bearing is defined as the frictional moment that must be overcome by the bearing to start rotating. Therefore, only the sliding frictional moment and the frictional moment of seals, if applied, must be taken into consideration. At an ambient temperature of 20 to 30 °C (70 to 85 °F), the starting torque can be calculated using

$$M_{\text{start}} = M_{\text{sl}} + M_{\text{seal}}$$

where

$M_{\text{start}}$  = starting frictional moment [Nmm]

$M_{\text{sl}}$  = sliding frictional moment [Nmm]

$M_{\text{seal}}$  = frictional moment of the seals [Nmm]

However, the starting torque can be considerably higher for roller bearings with a large contact angle. It can be up to four times higher for tapered roller bearings in the 313, 322 B, 323 B and T7FC series, and up to eight times higher for spherical roller thrust bearings.

### Power loss and bearing temperature

The power loss in a bearing as a result of bearing friction can be estimated using

$$N_R = 1,05 \times 10^{-4} M n$$

where

$N_R$  = power loss [W]

$M$  = total frictional moment of the bearing [Nmm]

$n$  = rotational speed [r/min]

The cooling factor  $W_s$  is defined as the heat being removed from the bearing per degree of temperature difference between the bearing and ambient. If the value of  $W_s$  is known, a rough estimate of the temperature increase in the bearing can be obtained using

$$\Delta T = N_R / W_s$$

where

$\Delta T$  = temperature increase [°C]

$N_R$  = power loss [W]

$W_s$  = cooling factor [W/°C]

# Basics of bearing speed

There is a limit to the speed at which rolling bearings can be operated. Generally, the temperature limit of the lubricant or the material of the bearing components sets the speed limit.

The speed at which a bearing reaches its operating temperature limit depends on the heat generated in the bearing, any externally applied heat, and the amount of heat that can be transferred away from the bearing.

The amount of heat generated in the bearing depends on the bearing type and size, internal design, load, lubrication and alignment. Other factors include cage design, accuracy and internal clearance.

In the product tables, two speeds are generally listed: reference speed (thermal) and limiting speed (mechanical).

In general, the limiting speed is higher than the reference speed for a bearing. For some bearing series, however, due to favourable frictional characteristics compared to the mechanical ability of the bearing to sustain high speeds, the reference speed can be higher than the limiting speed. In every case, however, the limiting speed of the bearing must always be observed, even under the most favourable operating conditions.

## Reference speed

The main purpose of the reference speed (thermal) is to provide a quick assessment of the speed capabilities of a bearing based on standardized reference values for the heat flow density as established in ISO 15312 (→ **diagram 1**).

This ISO standard provides reference operating conditions and standard values for the heat flow under those reference conditions. The standard reference heat flow densities shown in **diagram 1** are within the values found in bearing applications, shown as the shaded area.

To assess the actual temperature rise and heat flow in a particular application, a detailed analysis of the cooling conditions surrounding the bearing would be required. This is outside the scope of the present ISO speed rating standard. For detailed temperature rise calcu-

lations, contact the SKF application engineering service.

The values of the reference speeds are based on ISO 15312. The ISO standard, established for oil lubrication, is also valid for grease lubrication. Outer ring rotation is not covered by the ISO standard. Therefore, it may be necessary to reduce the reference speed ratings in applications where the outer ring rotates. For additional information, contact the SKF application engineering service.

For bearings with contact seals, speed capability of the bearing is not determined by the frictional heat generated in the rolling element / raceway contacts. Therefore, these bearings are not included in the ISO reference speed standard and only the limiting speeds are listed in the product tables.

The ISO reference speed is based on open bearings under the following operating conditions:

- light loads:
  - radial load  $P = 0,05 C_0$  for radial bearings
  - axial load  $P = 0,02 C_0$  for thrust bearings
- nominal temperature increase of  $50\text{ }^\circ\text{C}$  ( $90\text{ }^\circ\text{F}$ ) above an ambient reference temperature of  $20\text{ }^\circ\text{C}$  ( $70\text{ }^\circ\text{F}$ )
- good lubrication and clean conditions
- sufficient operating clearance (→ *Bearing internal clearance, page 149*)

Grease lubricated bearings may undergo a temperature peak during initial start-up, requiring a running-in period before they reach normal operating temperature.

D

## Speeds

### Influence of load and oil viscosity on reference speed

When load or viscosity values higher than the reference values are applied, the frictional resistance increases and the reference speed should be adjusted. Conversely, lower viscosity or load values can enable higher speeds.

The influence of load and kinematic viscosity on the reference speed can be estimated from the diagrams referenced in the following:

- for radial ball bearings (→ **diagram 2**)
- for radial roller bearings (→ **diagram 3, page 122**)
- for thrust ball bearings (→ **diagram 4, page 123**)
- for thrust roller bearings (→ **diagram 5, page 124**)

### Oil lubrication

Values for the adjustment factors for oil lubrication can be obtained from **diagrams 2 to 5** as a function of  $P/C_0$  and the bearing mean diameter  $d_m$ :

- $f_p$  for the influence of the equivalent dynamic bearing load  $P$
- $f_v$  for the influence of the viscosity

where

$P$  = equivalent dynamic bearing load [kN]

$C_0$  = basic static load rating [kN]

(→ **product tables**)

$d_m$  = bearing mean diameter [mm]  
=  $0,5 (d + D)$

The viscosity values in the diagrams are expressed with ISO designations, for example ISO VG 32, where 32 is the oil viscosity at 40 °C (105 °F).

The adjusted reference speed for oil lubrication can be estimated using

$$n_{ar} = n_r f_p f_v$$

where:

$n_{ar}$  = adjusted reference speed [r/min]

$n_r$  = nominal reference speed [r/min]

(→ **product tables**)

$f_p$  = adjustment factor for bearing load  $P$

$f_v$  = adjustment factor for oil viscosity

### Grease lubrication

The values for the adjustment factor for the bearing load ( $f_p$ ) provided in **diagrams 2 to 5** are also valid for grease lubrication. When greases with a base oil viscosity between 100 and 200 mm<sup>2</sup>/s at 40 °C (105 °F) are used, the value for the adjustment factor for the viscosity  $f_v = 1$ . For other base oil viscosities, the value for  $f_v$  needs to be compared with the value for ISO VG 150 oil. The adjusted reference speed for grease lubrication can be estimated using

$$n_{ar} = n_r f_p \frac{f_{v \text{ actual base oil viscosity}}}{f_{v \text{ ISO VG150}}}$$

Diagram 2

Adjustment factors  $f_p$  and  $f_v$  for radial ball bearings

Diagram 4

Adjustment factors  $f_p$  and  $f_v$  for thrust ball bearings

D

Adjustment factors  $f_p$  and  $f_v$  for thrust roller bearings

**Example 1**

An SKF Explorer 6210 deep groove ball bearing is lubricated via an oil bath. The oil viscosity is  $68 \text{ mm}^2/\text{s}$  at  $40 \text{ }^\circ\text{C}$  ( $105 \text{ }^\circ\text{F}$ ), load  $P = 0,24 C_0$ . What is the adjusted reference speed?

For bearing 6210:  $d_m = 0,5 (50 + 90) = 70 \text{ mm}$  and  $n_r = 15\,000 \text{ r/min}$ . From **diagram 2, page 121**, with  $d_m = 70 \text{ mm}$  and  $P/C_0 = 0,24$ ,  $f_P = 0,63$  and with  $P/C_0 = 0,24$  and ISO VG 68,  $f_v = 0,85$ .

$$n_{ar} = 15\,000 \times 0,63 \times 0,85 = 8\,030 \text{ r/min}$$

Note that the limiting speed for this bearing is  $10\,000 \text{ r/min}$ , which is higher than its adjusted reference speed. In cases like this, the lower of the two rated speeds is the most significant for the service life of the bearing. In general, speeds up to the adjusted reference speed provide conditions favourable for extended bearing service life. Higher speeds up to the bearing limiting speed can, in principle, be adopted after further assessment of the specific temperature conditions surrounding the bearing arrangement.

**Example 2**

A grease lubricated SKF Explorer 22222 E spherical roller bearing is subjected to a load  $P = 0,15 C_0$ . The grease has a base oil viscosity of  $220 \text{ mm}^2/\text{s}$  at  $40 \text{ }^\circ\text{C}$  ( $105 \text{ }^\circ\text{F}$ ). What is the adjusted reference speed?

For bearing 22222 E:  $d_m = 0,5 (110 + 200) = 155 \text{ mm}$  and  $n_r = 3\,000 \text{ r/min}$ . From **diagram 3, page 122**, with  $d_m = 155 \text{ mm}$  and  $P/C_0 = 0,15$ ,  $f_P = 0,53$  and with  $P/C_0 = 0,15$  and ISO VG 220,  $f_{n \text{ actual}} = 0,83$ ; with  $P/C_0 = 0,15$  and ISO VG 150,  $f_{v \text{ ISO VG150}} = 0,87$ .

$$n_{ar} = 3\,000 \times 0,53 \times 0,83/0,87 = 1\,520 \text{ r/min}$$

Up to this speed, the bearing thermal conditions are generally considered normal. Higher speeds, up to the limiting speed of  $4\,000 \text{ r/min}$ , can also be considered under certain circumstances. This would require an assessment of the temperature rise of the application based on the actual frictional and cooling conditions within the application. In cases like this, the lubricant, heat dissipation, bearing internal clearance and accuracy of the bearing seats must be verified and adapted to accommodate higher speeds. For these types of evaluations,

contact the SKF application engineering service.

**Speeds above the reference speed**

As mentioned in the previous example, it is possible to operate bearings at speeds above the reference speed provided the increase in operating temperature can be controlled and does not have a negative impact on the bearing or the application.

Prior to operating a bearing above its reference speed, make sure that all bearing components, including the cage(s) and seal(s), can accommodate the increased temperatures. Also, check that clearance or preload values and the lubricant can accommodate higher temperatures.

The operating temperature can be kept under control if friction within the bearing can be reduced or if heat can be removed from the bearing arrangement.

Friction can be reduced to some extent with an optimized lubrication system that applies accurately metered, small quantities of grease or oil to the bearing.

Heat can be removed from a bearing arrangement in a number of ways. Typical solutions to cool the oil in oil lubricated applications include fans, auxiliary coolers and circulating oil systems ( $\rightarrow$  *Oil lubrication methods, page 262*).

For bearings that accommodate axial displacement between one bearing ring and its seat, it is important to check that the bearing can move axially under actual operating conditions. In some cases, it may also be necessary to improve other speed-limiting factors such as bearing running accuracy, the cage design and bearing materials. Any increase in bearing temperature lowers the viscosity and effectiveness of the lubricant, making it more difficult for the lubricant to maintain an effective hydrodynamic film.

In most cases, this further increases friction and frictional heat. When temperatures increase to the point that the inner ring becomes significantly hotter than the outer ring, the operating clearance in the bearing can be reduced to the point that the bearing seizes. Any increase in speed above the reference speed generally means that the temperature difference between the inner and outer rings is

greater than normal. Therefore, a bearing with a larger internal clearance than initially selected might be required (→ *Bearing internal clearance*, **page 149**). It may also be necessary to look more closely at the temperature distribution in the bearing, as well as the temperature limits of the cage and lubricant as steady-state temperatures higher than 70 °C (160 °F) may reduce their service life (→ *Polymer cages*, **page 153** and *Lubricating greases*, **page 244**).

For specific assessments of applications operating above the reference speed (thermal), contact the SKF application engineering service. As a general rule, the limiting speed of the bearing must be observed even under the most favourable frictional and cooling conditions.

## Limiting speed

The limiting speed (mechanical) is determined by criteria that include the form stability or strength of the cage, lubrication of the cage guiding surfaces, centrifugal and gyrotory forces acting on the rolling elements, bearing-housing precision and other speed-limiting factors, such as seals and the lubricant for sealed bearings.

Experience shows that even under the most favourable loading and frictional conditions, there are maximum speeds that should not be exceeded for technical reasons or because of the very high costs involved in keeping the running conditions stable for any length of time.

The limiting speeds listed in the product tables are valid for the basic bearing design. In cases where the limiting speed is higher than the reference speed, temperatures significantly higher than the reference value can be expected. Under these conditions, appropriate measures might be necessary (→ *Speeds above the reference speed*, **page 125**). If these measures are not adequate, the bearing internal clearance and accuracy of the housing and shaft seats should be verified and adapted to the more demanding operating conditions (→ *Tolerances for total radial run-out*, **page 200**).

The compatibility of the materials in the bearing system must also be considered relative to the bearing temperature and required

service life (→ *Materials for rolling bearings*, **page 150** and *Lubricating greases*, **page 244**). When the steady state operating temperature is higher than the maximum recommended by the bearing material stabilization class, i.e. 120 °C (250 °F) for the SN class (→ *Influence of the operating temperature*, **page 82**), a bearing with a higher stabilization class might be necessary to maintain the mounting stress and bearing internal clearance.

For grease lubrication, additional factors such as lubrication of the cage guiding surfaces and grease consistency at the operating temperature should be taken into consideration (→ *Grease lubrication*, **page 242**).

Some open ball bearings have very low friction, and the reference speeds listed might be higher than the limiting speeds. Therefore, the adjusted reference speed needs to be calculated and compared to the limiting speed. The lower of the two values should be used.

To function satisfactorily, particularly at high speeds, bearings must be subjected to a given minimum load. For detailed information about the required minimum load, refer to *Loads* in the relevant product chapter.

In some special cases, such as for some cylindrical roller bearings, the choice of an alternative cage can make it possible to operate bearings at speeds higher than the limiting speed for the standard execution listed in the tables (→ *Permissible speed*, **table 9**, **page 600**).

In general, if the limiting speed is not able to meet the requirements of the application, modifications to the bearing, lubrication system or application may be required. Modifications could include improving bearing running accuracy, changing cage materials, changing the lubricant or lubrication method, or improving heat dissipation.

In that case, SKF recommends contacting the SKF application engineering service for assistance.

## Special cases

In certain applications, the speed limits are superseded in importance by other considerations.

### Slow speeds

At very slow speeds, it is very difficult for an elasto-hydrodynamic lubricant film to be built up in the contact areas between the rolling elements and raceways. In these applications, lubricants containing EP additives should be considered (→ *Grease lubrication*, **page 242**). Alternatively, consider the use of Solid Oil (→ **page 1185**).

### Oscillating movements

With this type of movement, the direction of rotation changes before the bearing has completed a single revolution. As the rotational speed is zero at the point where the direction of rotation is reversed, a full hydrodynamic lubricant film is impossible to maintain. As a result, SKF recommends using a lubricant containing an effective EP additive to maintain a boundary lubricant film capable of supporting the applied loads. Hybrid bearings (→ **page 1219**) perform well under insufficient lubrication conditions and can therefore provide favourable results in applications where rapid accelerations, decelerations and load reversals (directional changes) occur.

In general, it is not possible to give a limit or a rating for the speed of oscillating movements, as the upper limit is not dictated by a heat balance but by the inertial forces that come into play. With each reversal, there is a danger that inertia causes the rolling elements to slide for a short distance and smear the raceways. The accelerations and decelerations depend on the mass of the rolling elements and cage, the type and quantity of lubricant, the operating clearance and the loads on the bearing.

D

### Vibration generation at high speeds

When bearings operate at high speeds, high over-rolling frequencies are generated in the bearing and a high-pitched noise can be expected from the application. What is perceived as “bearing noise” is the audible effect of the vibration generated by the bearing and transmitted through the surrounding structure. The surrounding structure also contributes to the attenuation or amplification of the noise characteristics of the application. In addressing noise issues in high-speed bearing applications, it is useful to consider the following additional aspects.

#### Excitation due to a varying number of loaded rolling elements

When a radial load is applied to a bearing, the number of rolling elements carrying the load varies slightly during operation, this means alternating between 2–3–2–3. This generates a displacement in the direction of the load. The resulting vibration cannot be avoided, but can be reduced by applying an axial preload to load all the rolling elements. This, however, is not possible for cylindrical roller, needle roller and CARB toroidal roller bearings and is not recommended for double-row bearings.

#### Accuracy of associated components

In cases where there is a tight fit between the bearing ring and the housing or shaft, the bearing ring may take the shape of the adjacent component. If form deviations are present, these may cause vibrations during operation. Therefore, it is important to machine the shaft and housing seats to the required tolerances (→ *Tolerances for total radial run-out*, page 200).

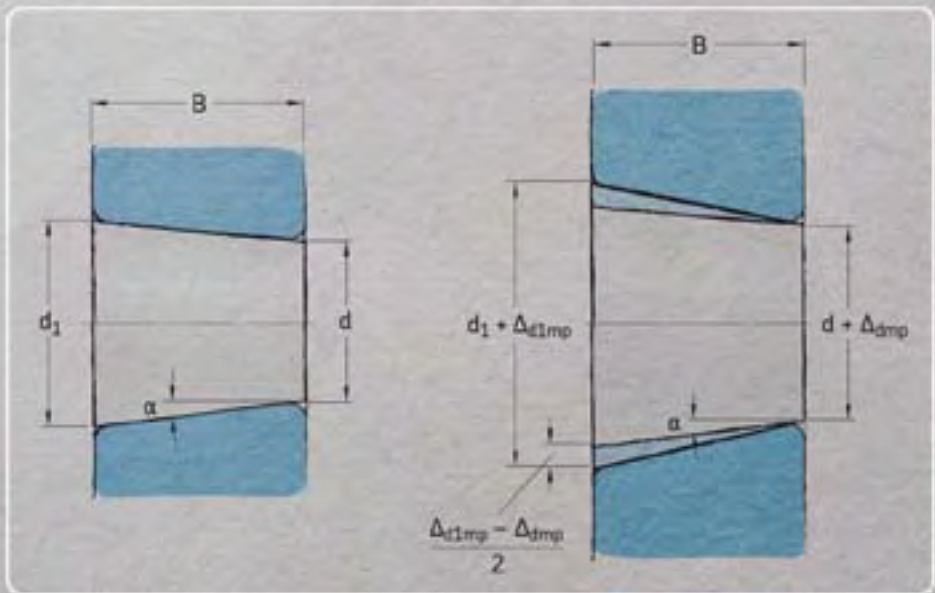

Presence of local raceway damage or indentations caused by solid contaminants also reduce the accuracy of the raceway micro-geometry and increase vibrations in the bearing. High cleanliness of the lubricant and protection from solid contaminants can help to reduce bearing noise issues in an application.

#### Influence of the bearing on the vibration behaviour of the application

In many applications, bearing stiffness is of the same order as the stiffness of the surrounding structure. This opens the possibility of reducing vibrations in an application by either replacing the bearing or adjusting the preload or clearance in the bearing arrangement. There are three ways to reduce vibration:

- Remove the critical excitation vibration from the application.
- Dampen the critical excitation vibration between excitant component and resonant components.
- Change the stiffness of the structure to change the critical frequency.

## Dimensions

For information about main dimensions of a bearing, refer to *Boundary dimensions* (→ page 40).

### Chamfer dimensions

Minimum values for the chamfer dimensions (→ fig. 1) in the radial direction ( $r_1, r_3$ ) and the axial direction ( $r_2, r_4$ ) are listed in the product tables. These values are in accordance with the general plans listed in the following standards:

- ISO 15, ISO 12043 and ISO 12044 for radial rolling bearings
- ISO 355 for radial tapered roller bearings
- ISO 104 for thrust rolling bearings

The appropriate maximum chamfer limits that are important when dimensioning fillet radii are in accordance with ISO 582 (→ *Tolerances*).

Fig. 1

## Tolerances

The dimensional and running accuracy of rolling bearings has been standardized internationally. In addition to the Normal tolerances, the ISO standards also cover closer tolerances, such as:

- tolerance class 6, which corresponds to SKF P6 tolerance class
- tolerance class 5, which corresponds to SKF P5 tolerance class

For special applications like machine tool spindles, SKF also manufactures bearings with higher accuracy. These include the P4, P4A, PA9A, SP and UP tolerance classes. For additional information, refer to *Super-precision bearings* (→ [skf.com/super-precision](http://skf.com/super-precision)).

For tolerance information about each bearing type, refer to *Tolerances* in the relevant product chapter. Bearings with higher accuracy than Normal are typically identified by a designation suffix for the tolerance class.

### Tolerance symbols

The tolerance symbols and their definitions are provided in **table 1** (→ page 134).

### Diameter series identification

The bore and outside diameter variation tolerances  $V_{dp}$  and  $V_{Dp}$  for metric rolling bearings (→ **tables 3 to 5, pages 137 to 139** – except tapered roller bearings) are not universally valid for all diameter series. To determine the diameter series of a radial bearing, refer to **table 2** (→ page 136).

## Tolerance tables

The actual tolerances are listed in the tables referenced in the following:

- Normal tolerances for radial bearings, except tapered roller bearings (→ **table 3, page 137**)
- P6 class tolerances for radial bearings, except tapered roller bearings (→ **table 4, page 138**)
- P5 class tolerances for radial bearings, except tapered roller bearings (→ **table 5, page 139**)
- Normal and CL7C class tolerances for metric tapered roller bearings (→ **table 6, page 140**)
- CLN class tolerances for metric tapered roller bearings (→ **table 7, page 141**)
- P5 class tolerances for metric tapered roller bearings (→ **table 8, page 142**)
- Tolerances for inch tapered roller bearings (→ **table 9, page 143**)
- Tolerances for thrust bearings (→ **table 10, page 144**)
- Normal, P6 and P5 class tolerances for tapered bore, taper 1:12 (→ **table 11, page 145**)
- Normal tolerances for tapered bore, taper 1:30 (→ **table 12, page 146**)

Where standardized, the values are in accordance with ISO 492, ISO 199 and ANSI/ABMA Std 19.2.

## Chamfer dimension limits

To prevent the improper dimensioning of fillets on associated components for rolling bearings and facilitate calculations to locate retaining rings, the maximum chamfer limits (→ **fig. 2**) for the relevant minimum chamfer dimensions (→ **product tables**) are listed in the following tables:

- chamfer dimension limits for metric radial and thrust bearings, except tapered roller bearings (→ **table 13, page 147**)
- chamfer dimension limits for metric radial tapered roller bearings (→ **table 14, page 147**)
- chamfer dimension limits for inch tapered roller bearings (→ **table 15, page 148**)

The limits for metric bearings are in accordance with ISO 582. The limits for inch tapered roller bearings, which differ considerably from those for metric bearings, are described in ANSI/ABMA 19.2, but are not standardized.

### Example

What is the largest radial value ( $r_{1\max}$ ) for the chamfer of a 6211 deep groove ball bearing? From the product table (→ **page 328**),

$r_{1\min} = 1,5$  mm and  $d = 55$  mm.

From **table 13** (→ **page 147**) with  $r_{s\min} = 1,5$  mm and  $d < 120$  mm, the largest radial value  $r_{1\max} = 2,3$  mm.

## Bearing internal clearance

Bearing internal clearance (→ **fig. 3**) is defined as the total distance through which one bearing ring can be moved relative to the other in the radial direction (radial internal clearance) or in the axial direction (axial internal clearance).

It is necessary to distinguish between initial internal clearance in the bearing prior to mounting and operating internal clearance, which applies to a bearing in operation that has reached a stable temperature.

In almost all applications, the initial clearance in a bearing is greater than its operating clearance. The difference can be attributed to the need for an interference fit on the shaft and/or in the housing, combined with thermal expansion of the bearing rings and associated components.

Sufficient internal clearance in a bearing during operation is extremely important if the bearing is to operate satisfactorily. As a general rule, ball bearings should have an operating clearance (or preload) that is virtually zero. Cylindrical, needle, spherical and CARB toroidal roller bearings, on the other hand, should always have some residual (radial) clearance – however small – in operation. The same is true for tapered roller and angular contact ball bearings. However, in applications where a high degree of stiffness is required, tapered roller and angular contact ball bearings can be mounted with a certain amount of preload (→ *Bearing preload*, **page 214**).

E

The initial internal clearance referred to as Normal implies that a suitable operating clearance can be obtained if the recommended shaft and housing fits are realized during mounting and operating conditions are normal. Where operating and mounting conditions differ from normal, for example, when interference fits are used for both bearing rings or considerable temperature differences prevail, bearings with greater or smaller internal clearance than Normal are required. In these cases, SKF recommends checking residual (radial) clearance in the bearing after it has been mounted.

Bearings with an internal clearance other than Normal are identified by the suffixes C1 to C5 (→ **table 16**).

The clearance values for the various bearing types are listed in the relevant product chapters and are valid for unmounted bearings. For paired (universally matchable) single row angular contact ball bearings and tapered roller bearings, double row angular contact ball bearings and four-point contact ball bearings, values for the axial internal clearance are listed instead of radial clearance, as the axial clearance is of greater importance for these bearing types.

For additional information about clearance or preload, refer to *Selecting internal clearance or preload* (→ **page 212**).

## Materials for rolling bearings

The materials from which bearing components are made, determine, to a large extent, the performance and reliability of the bearing. For the bearing rings and rolling elements, typical considerations include hardness for load carrying capacity, fatigue resistance in the rolling contact area, under clean or contaminated lubrication conditions, and the dimensional stability of the bearing components. For the cage, considerations include friction, strain, inertial forces, and in some cases, the chemical action of certain lubricant additives, solvents, coolants and refrigerants. The relative importance of these considerations can be affected by other operational parameters including moisture, elevated temperatures, shock loads or a combination of these and other conditions.

Rolling bearings with integral contact seals can also have a considerable impact on the performance and reliability of the bearings. Their materials must be able to resist heat, chemicals and oxidation. Bearings that are capped on both sides normally are lubricated for life. For detailed information about lubrication and lubricants, refer to *Lubrication* (→ **page 239**).

SKF has the competence and facilities to provide a variety of materials, processes and coatings. Therefore, SKF application engineers can assist in selecting materials that can provide superior performance for a particular application.

Table 16

### Supplementary designation for internal clearance

Suffix	Internal clearance
C1	Smaller than C2
C2	Smaller than Normal
CN	Normal, only used together with an additional letter that identifies a reduced or displaced clearance range.
C3	Greater than Normal
C4	Greater than C3
C5	Greater than C4

## Materials for bearing rings and rolling elements

### Bearing steels for through-hardening

The most common steel for through-hardening is a carbon chromium steel, containing approximately 1% carbon and 1,5% chromium, in accordance with ISO 683-17. Today, carbon-chromium steel is one of the oldest and most intensively investigated steels due to the continuously increasing demands for extended bearing service life. The composition of this bearing steel provides an optimum balance between manufacturing and application performance. This steel normally undergoes a martensitic or bainitic heat treatment to obtain a hardness between 58 and 65 HRC.

Within the last few years, process developments have enabled more stringent cleanliness specifications to be realized, which has had a significant impact on the consistency and quality of SKF's bearing steel. The reduction of oxygen and harmful non-metallic inclusions has led to significantly improved properties of rolling bearing steels – the steels from which SKF Explorer bearings are made.

### Bearing steels for induction-hardening

Surface induction-hardening offers the possibility to selectively harden a component's raceway, while leaving the remainder of the component unaffected by the hardening process. The steel grade and the manufacturing processes used prior to surface induction-hardening dictate the properties in the unaffected areas, which means that a combination of properties can be achieved in one component.

An example of this is the flanged wheel hub bearing unit (HBU), where the properties of the unhardened flange must resist structural fatigue, while the raceways are hardened to resist rolling contact fatigue.

### Bearing steels for case-hardening

Chromium-nickel and manganese-chromium alloyed steels in accordance with ISO 683-17 with a carbon content of approximately 0,15% are the steels most commonly used for case-hardened SKF rolling bearing components.

In applications where there are high tensile interference fits and heavy shock loads, SKF recommends bearings with case-hardened rings and/or rolling elements.

### Stainless steels

The most common stainless steels used for SKF bearing rings and rolling elements are high chromium content steels like X65Cr14 in accordance with ISO 683-17 and X105CrMo17 in accordance with EN 10088-1.

It should be noted that for some applications, corrosion resistant coatings might be an excellent alternative to stainless steel. For additional information about alternative coatings, contact the SKF application engineering service.

### High-temperature bearing steels

Depending on the bearing type, standard bearings made of steels for through-hardening and surface-hardening have a recommended maximum operating temperature, which ranges between 120 and 200 °C (250 to 390 °F). The maximum operating temperature is directly related to the heat treat process.

For operating temperatures up to 250 °C (480 °F), a special heat treat (stabilization) process can be applied. In this case, however, the process reduces the load carrying capacity of the bearing, which must be taken into consideration.

For bearings operating at elevated temperatures above 250 °C (480 °F) for extended periods, highly alloyed steels like 80MoCrV42-16, manufactured in accordance with ISO 683-17, should be used. This steel, which retains its hardness, enables the bearing to maintain its performance characteristics even under extreme temperature conditions.

For additional information about high-temperature bearing steels, contact the SKF application engineering service.

## Bearing specifics

### Ceramics

The common ceramic used for SKF bearing rings and rolling elements is a bearing grade silicon nitride material in accordance with ISO 26602. It consists of fine elongated grains of beta-silicon nitride in a glassy phase matrix. It provides a combination of favourable properties for rolling bearings, such as high hardness, low density, low coefficient of thermal expansion, high electric resistivity, low dielectric constant and no response to magnetic fields (→ **table 17**).

### Cage materials

#### Stamped metal cages

##### Sheet steel cages

The majority of stamped sheet steel cages are made of continuously hot-rolled low carbon steel in accordance with EN 10111. These lightweight cages have relatively high strength and can be surface treated to further reduce friction and wear.

Stamped cages normally used in stainless steel bearings are made of X5CrNi18-10 stainless steel, in accordance with EN 10088-1.

##### Sheet brass cages

Stamped sheet brass cages are used for some small and medium-size bearings. The brass used for these cages is in accordance with EN 1652. In applications like refrigeration compressors that use ammonia, season cracking in sheet brass might occur, therefore machined brass or steel cages should be used instead.

## Machined metal cages

### Machined steel cages

Machined steel cages are normally made of non-alloyed structural S355GT (St 52) type steel in accordance with EN 10 025:1990 + A:1993. To improve sliding and wear-resistance properties, some machined steel cages are surface treated.

Machined steel cages are used for large bearings or in applications where there is a danger that season cracking, caused by a chemical reaction, may occur if a brass cage is used. Steel cages can be used at operating temperatures up to 300 °C (570 °F). They are not affected by the mineral or synthetic oil-based lubricants normally used for rolling bearings, or by the organic solvents used to clean bearings.

### Machined brass cages

Most brass cages are machined from a CW612N cast or wrought brass in accordance with EN 1652. They are unaffected by most common bearing lubricants, including synthetic oils and greases, and can be cleaned using normal organic solvents. Brass cages should not be used at temperatures above 250 °C (480 °F).

## Polymer cages

### Polyamide 66

For the majority of injection moulded cages, polyamide 66 (PA66) is used. This material, with or without glass fibres, is characterized by a favourable combination of strength and elasticity. The mechanical properties like strength and elasticity of polymer materials are temperature dependent and subject to ageing. The most important factors that play a role in the ageing process are temperature, time and the medium (lubricant) to which the polymer is exposed. **Diagram 1** shows the relationship between these factors for glass fibre reinforced PA66. It shows that cage life decreases with increasing temperature and the aggressiveness of the lubricant.

Diagram 1

E

## Bearing specifics

Therefore, whether polyamide cages are suitable for a specific application depends on the operating conditions and life requirements. The classification of lubricants into “aggressive” and “mild” is reflected by the “permissible operating temperature” for cages made of glass fibre reinforced PA66 with various lubricants (→ **table 18**). The permissible operating temperature in **table 18** is defined as the temperature that provides a cage ageing life of at least 10 000 operating hours.

Some media are even more “aggressive” than those provided in **table 18**. A typical example is ammonia, used as a refrigerant in compressors. In those cases, cages made of glass fibre reinforced PA66 should not be used at operating temperatures above 70 °C (160 °F).

Polyamide also has a low temperature limit because it loses its elasticity, which can cause cage failures under extremely cold conditions. As a result, cages made of glass fibre reinforced PA66 should not be used in applications where

the continuous operating temperature is below -40 °C (-40 °F).

In applications where a high degree of toughness is a critical operational parameter, such as in railway axleboxes, a super-tough modified PA66 can be used. For additional information, contact the SKF application engineering service.

**Table 18**

### Permissible operating temperatures for PA66 cages with various bearing lubricants

Lubricant	Permissible operating temperature <sup>1)</sup>	
	°C	°F
-		
<b>Mineral oils</b>		
Oils without EP additives, e.g. machine or hydraulic oils	120	250
Oils with EP additives, e.g. industrial and automotive gearbox oils	110	230
Oils with EP additives, e.g. automotive rear axle and differential gear oils (automotive), hypoid gear oils	100	210
<b>Synthetic oils</b>		
Polyglycols, poly- $\alpha$ -olefins	120	250
Diesters, silicones	110	230
Phosphate esters	80	175
<b>Greases</b>		
Lithium greases	120	250
Polyurea, bentonite, calcium complex greases	120	250

For sodium and calcium greases and other greases with a maximum operating temperature  $\leq 120$  °C (250 °F), the maximum temperature for a polyamide cage is the same as the maximum operating temperature for the grease.

<sup>1)</sup> Measured on the outside surface of the outer ring; defined as the temperature that provides a cage ageing life of at least 10 000 operating hours.

**Polyamide 46**

Glass fibre reinforced polyamide 46 (PA46) is the standard cage material for some small and medium-size CARB toroidal roller bearings. The permissible operating temperature is 15 °C (25 °F) higher than for glass fibre reinforced PA66.

**Polyetheretherketone**

The use of the glass fibre reinforced polyetheretherketone (PEEK) has become more popular for demanding conditions regarding high speeds, chemical resistance or high temperatures. The exceptional properties of PEEK provide a superior combination of strength and flexibility, high operating temperature range, high chemical and wear-resistance and good processability. Due to these outstanding features, PEEK cages are available as standard for some ball and cylindrical roller bearings, such as hybrid and/or super-precision bearings. The material does not show signs of ageing by temperature or oil additives up to 200 °C (390 °F). However, the maximum temperature for high-speed use is limited to 150 °C (300 °F) as this is the softening temperature of the polymer.

**Phenolic resin**

Lightweight, fabric reinforced phenolic resin cages can withstand heavy inertial forces, but are not able to accommodate high operating temperatures. In most cases, these cages are used as standard in super-precision angular contact ball bearings.

**Cages made of other materials**

In addition to the materials described above, SKF bearings for special applications may be fitted with cages made of other engineered polymers, light alloys or special cast iron. For additional information about alternative cage materials, contact the SKF application engineering service.

**Seal materials**

Seals integrated in SKF bearings are typically made of elastomers. The type of material can depend on the series and size of the bearing as well as the application requirements. SKF seals are generally made of the materials listed below.

**Acrylonitrile-butadiene rubber**

Acrylonitrile-butadiene rubber (NBR) is the “universal” seal material. This copolymer, manufactured from acrylonitrile and butadiene, has good resistance to the following media:

- most mineral oils and greases with a mineral oil base
- normal fuels, such as petrol, diesel and light heating oils
- animal and vegetable oils and fats
- hot water

It also can tolerate dry running of the lip for short periods. The permissible operating temperature range is -40 to +100 °C (-40 to +210 °F). Temperatures up to 120 °C (250 °F) can be tolerated for brief periods. At higher temperatures, the material hardens.

E

### Hydrogenated acrylonitrile-butadiene rubber

Hydrogenated acrylonitrile-butadiene rubber (HNBR) has appreciably better wear-characteristics than NBR so that seals made of this material have a longer service life. HNBR is also more resistant to heat, ageing and hardening in hot oil or ozone exposure.

The upper operating temperature limit is 150 °C (300 °F), which is appreciably higher than that of NBR.

### Fluoro rubber

Fluoro rubbers (FKM) are characterized by their high thermal and chemical resistance. Their resistance to ageing and ozone is very good and their gas permeability is very slight. They have exceptionally good wear-characteristics even under harsh environmental conditions and can withstand operating temperatures up to 200 °C (390 °F). Seals made of this material can tolerate dry running of the lip for short periods.

FKM is also resistant to oils and hydraulic fluids, fuels and lubricants, mineral acids and aliphatic as well as aromatic hydrocarbons which would cause seals made of other materials to fail. In the presence of esters, ethers, ketones, certain amines and hot anhydrous hydrofluorides, FKM should not be used.

Seals made of FKM exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled. Read and follow the safety precautions (→ **WARNING**).

## WARNING

### Safety precautions for fluoro rubber and Polytetrafluoroethylene

Fluoro rubber (FKM) and Polytetrafluoroethylene (PTFE) are very stable and harmless under normal operating conditions up to 200 °C (390 °F). However, if exposed to extreme temperatures above 300 °C (570 °F), such as fire or the open flame of a cutting torch, FKM and PTFE give off hazardous fumes. These fumes can be harmful if inhaled, as well as if they contact the eyes. In addition, once the seals have been heated to such temperatures, they are dangerous to handle even after they have cooled. Therefore, they should never come in contact with the skin. If it is necessary to handle bearings with seals that have been subjected to high temperatures, such as when dismounting the bearing, the following safety precautions should be observed:

- Always wear protective goggles, gloves and an appropriate breathing apparatus.
- Place the remains of the seals in an airtight plastic container marked with a symbol for “material will etch”.
- Follow the safety precautions in the appropriate material safety data sheet (MSDS).

If there is unintentional contact with the seals, wash hands with soap and plenty of water and flush eyes with plenty of water and consult a doctor immediately. If the fumes have been inhaled, consult a doctor immediately.

The user is responsible for the correct use of the product during its service life and its proper disposal. SKF takes no responsibility for the improper handling of FKM or PTFE, or for any injury resulting from their use.

## Polyurethane

Polyurethane (PUR) is a wear-resistant organic material which has good elastic properties. It withstands operating temperatures from  $-20$  up to  $+80$  °C ( $-5$  to  $175$  °F). It has good resistance to mineral oil-based greases, mineral oils with no or a low proportion of EP additives, water and water-oil mixtures. It is not resistant to acids, alkalis or polar solvents.

## Lubricants

Capped bearings normally have a factory grease fill. The lubricant is an integral part of the bearing. For additional information, refer to the relevant product chapter.

## Coatings

Coating is a well-established method to upgrade materials and to provide bearings with additional benefits for specific application conditions. Two different coating methods developed by SKF are available and have been proven successful in many applications.

NoWear is a wear-resistant surface coating that applies a low-friction carbon coating on the bearing inner ring raceway(s) and/or the rolling elements. It can withstand long periods of operation under marginal lubrication conditions. For additional information, refer to *NoWear coated bearings* (→ **page 1241**).

INSOCOAT bearings are standard bearings that have the external surfaces of their inner or outer ring plasma-sprayed with an aluminium oxide to form a coating. It offers resistance to the damage that can be caused by the passage of stray electric current through the bearing. For additional information, refer to *INSOCOAT bearings* (→ **page 1205**).

Other coatings like zinc chromate, for example, can offer an alternative to stainless steel bearings in a corrosive environment, especially for ready-to-mount bearing units.

## Bearing systems

A bearing system, which is typically used to support a rotating shaft, generally requires two bearing arrangements – one at each end of the shaft. Depending on the requirements, such as stiffness or load directions, a bearing arrangement consists of one or more (matched) bearings. Typically, the purpose of a bearing system is to support and locate the shaft radially and axially, relative to stationary components, like housings. Depending on the application, loads, requisite running accuracy and cost considerations, various bearing systems can be designed:

- a locating/non-locating bearing system
- an adjusted bearing system
- a “floating” bearing system

Bearing systems consisting of a single bearing that can support radial, axial and moment loads, e.g. for an articulated joint, are not covered in this catalogue. For information about these bearing systems, contact the SKF application engineering service.

### Locating/non-locating bearing system

A locating/non-locating bearing system in a typical industrial application is designed to accommodate thermal expansion and contraction of a shaft. In this system, the bearing arrangement at one end of the shaft must be able to locate the shaft axially. This is accomplished by securing one bearing axially on the shaft and in the housing. The bearing arrangement on the opposite end of the shaft is non-locating and is designed to accommodate thermal displacements of the shaft relative to the housing to avoid induced internal loads.

For the locating bearing position, radial bearings that can accommodate combined (radial and axial) loads are used. These include deep groove ball bearings, double row or matched single row angular contact ball bearings, self-aligning ball bearings, spherical roller bearings, matched tapered roller bearings, NUP design cylindrical roller bearings, or NJ design cylindrical roller bearings mounted with an HJ angle ring.

Alternatively, the bearing arrangement in the locating position can consist of a combination of two bearings:

- A radial bearing that only accommodates radial load, such as a cylindrical roller bearing that has one ring without flanges.
- A bearing that provides axial location, such as a deep groove ball bearing, a four-point contact ball bearing, or a double direction thrust bearing.

The bearing that locates the shaft axially must not be located radially and is typically mounted with a small radial gap in the housing.

There are two ways to accommodate thermal displacements of the shaft at the non-

Fig. 1

Fig. 2

locating bearing position. The first is to use a bearing that only accommodates radial loads and enables axial displacement within the bearing. These include CARB toroidal roller bearings, needle roller bearings and cylindrical roller bearings that have one ring without flanges. The other method is to use a radial bearing mounted with a small radial gap in the housing so that the outer ring is free to move axially.

From the large number of locating/non-locating bearing combinations, the popular ones are listed in the following.

For stiff bearing arrangements requiring “frictionless” axial displacement within a bearing, the following combinations should be considered:

- deep groove ball bearing / cylindrical roller bearing (→ **fig. 1**)
- double row angular contact ball bearing / NU or N design cylindrical roller bearing (→ **fig. 2**)
- matched single row tapered roller bearings / NU or N design cylindrical roller bearing (→ **fig. 3**)
- NUP design cylindrical roller bearing / NU design cylindrical roller bearing (→ **fig. 4**)
- NU design cylindrical roller bearing and a four-point contact ball bearing / NU design cylindrical roller bearing (→ **fig. 5**)

Fig. 3

Fig. 4

Fig. 5

F

## Design considerations

For the bearing systems listed above, angular misalignment of the shaft relative to the housing must be kept to a minimum. If this is not possible, SKF recommends a self-aligning bearing system comprised of either:

- spherical roller bearing / CARB toroidal roller bearing (→ **fig. 6**)
- self-aligning ball bearing / CARB toroidal roller bearing

The ability of this bearing system to accommodate angular misalignment of the shaft relative to the housing, as well as axial displacement of the shaft within the CARB bearing, avoids induced internal axial loads in the bearing system.

For bearing systems with a rotating inner ring load, where changes in the shaft length are to be accommodated between the bearing and its seat, axial displacement should take place between the bearing outer ring and its housing. The most common combinations are:

- deep groove ball bearing / deep groove ball bearing (→ **fig. 7**)
- self-aligning ball or spherical roller bearing / self-aligning ball or spherical roller bearing (→ **fig. 8**)
- matched single row angular contact ball bearings / deep groove ball bearing (→ **fig. 9**)

### Adjusted bearing system

In an adjusted bearing system, the shaft is located axially in one direction by one bearing arrangement and in the opposite direction by the other. This system is referred to as cross-located and is generally used for short shafts. The most suitable bearings are:

- angular contact ball bearings (→ **fig. 10**)
- tapered roller bearings (→ **fig. 11**)

In a number of cases where single row angular contact ball bearings or tapered roller bearings are used for a cross-locating bearing system preload may be necessary (→ *Bearing preload*, **page 214**).

Fig. 10

Fig. 11

## Design considerations

### “Floating” bearing system

Like an adjusted bearing system, a “floating” bearing system is also cross-locating. However, a “floating” bearing system is more suitable for applications where axial stability of the shaft is less demanding or where other components on the shaft locate it axially. Suitable bearings for this system are:

- deep groove ball bearings (→ fig. 12)
- self-aligning ball bearings
- spherical roller bearings

In this system, it is important that one ring of each bearing, preferably the outer ring, is able to move axially on its seat. A “floating” bearing system can also be obtained with two NJ design cylindrical roller bearings used in mirrored arrangements with offset rings (→ fig. 13). In this case, axial displacement can occur within the bearings.

Fig. 12

Fig. 13

## Radial location of bearings

If the load carrying ability of a bearing is to be fully exploited, its rings or washers should be fully supported around their complete circumference and across the entire width of the raceway. The support, which should be firm and even, can be provided by a cylindrical or tapered seat or, for thrust bearing washers, by a flat (plane) support surface. This means that bearing seats should be manufactured to adequate tolerance classes and uninterrupted by grooves, holes or other features. In addition, the bearing rings should be reliably secured to prevent them from turning on or turning in their seats under load.

In general, satisfactory radial location and adequate support can only be obtained when the rings are mounted with an appropriate degree of interference (→ *Bearing clearance*, page 213 and *Bearing preload*, page 214). Inadequately or incorrectly secured bearing rings generally can cause damage to the bearing system. However, when axial displacement (as with a non-locating bearing) or easy mounting and dismantling are required, an interference fit cannot always be used. In cases where a loose fit is required, special precautions are necessary to limit the inevitable wear from creep (turning). This can be done, for example, by surface hardening the bearing seat and abutments, lubricating mating surfaces via special lubrication grooves, or providing locating slots in the bearing ring side faces to accommodate keys or other holding devices (→ fig 12).

### Selecting fits for bearings with a cylindrical bore

When selecting fits for bearings with a cylindrical bore, the information provided in this section should be considered, together with the general guidelines in the section thereafter.

#### 1. Conditions of rotation

Conditions of rotation refer to the bearing ring being considered relative to the direction of the load (→ table 1, page 166). Essentially, there are three different conditions:

- rotating load
- stationary load
- direction of load indeterminate

Rotating loads pertain if either the ring or the direction of the applied load is stationary while the other rotates. Heavy loads that do not rotate but oscillate, such as loads acting on connecting rod bearings, are generally considered to be rotating loads. A bearing ring subjected to a rotating load creeps on its seat if mounted with a too loose fit, and leads to wear and/or fretting corrosion of the contact surfaces. To prevent this, an adequate interference fit between the rotating ring and its seat must be used. The degree of interference is dictated by the operating conditions (→ points 2 and 4 below).

Stationary loads pertain if either both the bearing ring and the direction of the applied load are stationary or both are rotating at the same speed. Under these conditions, a bearing ring normally does not turn on its seat. Therefore, the ring does not need to have an interference fit, unless it is required for other reasons.

Direction of load indeterminate refers to variable external loads, shock loads, vibrations and unbalanced loads in high-speed applications. These give rise to changes in the direction of load, which cannot be accurately described. When the direction of load is indeterminate and particularly where heavy loads are involved, SKF recommends an interference fit for both rings. For the inner ring, the recommended fit for a rotating load is normally used. However, when the outer ring must be free to move axially in the housing, and the load is not heavy, a somewhat looser fit than that recommended for a rotating load can be used.

## Design considerations

### 2. Magnitude of the load

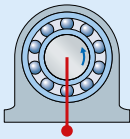

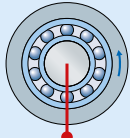

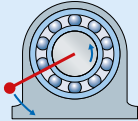

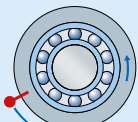

The degree of interference between the inner ring and the shaft seat must be selected based on the magnitude of the load on the bearing. Typically, the inner ring of a bearing deforms proportionately to the load. This deformation can loosen the interference fit between the inner ring and shaft, causing the ring to creep (turn) on its shaft seat. The heavier the load, the tighter the interference fit required (→ **fig. 14**). An interference fit has an influ-

ence on the bearing clearance or preload (→ *Bearing clearance*, **page 213** and *Bearing preload*, **page 214**). Shock loads and vibration also need to be considered, as a tighter fit might be necessary under these conditions.

Magnitude of bearing load is defined as:

- light load:  $P \leq 0,05 C$
- normal load:  $0,05 C < P \leq 0,1 C$
- heavy load:  $0,1 C < P \leq 0,15 C$
- very heavy load:  $P > 0,15 C$

Table 1

Conditions of rotation and loading				
Operating conditions	Schematic illustration	Load condition	Example	Recommended fits
Rotating inner ring Stationary outer ring Constant load direction		Rotating load on the inner ring Stationary load on the outer ring	Belt driven shafts	Interference fit for the inner ring Loose fit for the outer ring possible
Stationary inner ring Rotating outer ring Constant load direction		Stationary load on the inner ring Rotating load on the outer ring	Conveyor idlers Car wheel hub bearings	Loose fit for the inner ring possible Interference fit for the outer ring
Rotating inner ring Stationary outer ring Load rotates with the inner ring		Stationary load on the inner ring Rotating load on the outer ring	Vibratory applications Vibrating screens or motors	Interference fit for the outer ring Loose fit for the inner ring possible
Stationary inner ring Rotating outer ring Load rotates with the outer ring		Rotating load on the inner ring Stationary load on the outer ring	Gyratory crusher (Merry-go-round drivers)	Interference fit for the inner ring Loose fit for the outer ring possible

### 3. Bearing internal clearance

Bearings with an interference fit on a shaft or in a housing elastically deform (expand or compress) the ring to reduce the bearing internal clearance. However, a certain minimum clearance should remain (→ *Bearing clearance*, page 213). The interference fit can be so tight that bearings with an initial clearance that is greater than Normal have to be used to prevent unwanted preload (→ fig. 15).

### 4. Temperature differences

In many applications, the inner ring temperature is higher than the outer ring temperature. This can reduce internal clearance (→ fig. 16 and *Bearing clearance*, page 213) or increase preload (→ *Bearing preload*, page 214).

In operation, bearing rings normally reach a temperature that is higher than that of the components to which they are fitted. This can loosen the fit of the inner ring on its seat, while outer ring expansion can prevent the desired axial displacement of the ring in its housing. Fast start-ups can also loosen the inner ring fit when frictional heat generated by the bearing is not dissipated quickly enough. In some cases, friction from bearing seals can generate enough heat to loosen the inner ring fit.

Temperature differences and the direction of heat flow in the bearing arrangement must be taken into consideration.

### 5. Running accuracy

For applications requiring a high degree of running accuracy, interference fits are recommended. Loose fits can reduce stiffness and contribute to vibration. Bearing seats should conform at least to IT5 tolerance grade for the shaft and IT6 tolerance grade for the housing. Tight total run-out tolerances should also be applied (→ table 11, page 202).

Fig. 14

Fig. 15

Fig. 16

## Design considerations

### 6. Design and material of the shaft and housing

The fit of a bearing ring on its seat must not distort the ring (out-of-round). This can be caused, for example, by discontinuities in the seat surface. Therefore, SKF generally does not recommend split housings where outer rings require a tight, M7 or even tighter, interference fit.

The selected tolerance class for a split housing should not result in a fit tighter than that obtained with tolerance group H (or at most, tolerance group K).

To provide adequate support for bearing rings mounted in thin-walled housings, light alloy housings or on hollow shafts, tighter interference fits than those normally recommended for thick-walled steel or cast iron housings or for solid shafts should be used (→ *Fits for hollow shafts*, page 176). Also, sometimes interference fits that are not so tight may be required if the shaft material has a higher coefficient of thermal expansion than standard steel.

### 7. Ease of mounting and dismounting

Bearings with a loose fit are usually easier to mount and dismount than those with interference fits. In applications that require interference fits and relatively easy mounting and dismounting, separable bearings or bearings with a tapered bore should be considered (→ *Bearings with a tapered bore*). Bearings with a tapered bore can be mounted on adapter or withdrawal sleeves on plain or stepped shafts, or mounted directly on a tapered shaft seat (→ **figs. 25 to 27**, page 207).

### 8. Displacement of the bearing in the non-locating position

If bearings in the non-locating position cannot accommodate axial displacement internally (within the bearing), the outer ring must be free to move axially on its seat at all times. To do this, the ring that carries a stationary load can have a loose fit (→ **fig. 20**, page 205). For some particular applications, where the outer ring is under stationary load and the bearing must move axially in the housing seat to accommodate displacement, a hardened intermediate bushing or sleeve can be fitted in the housing bore to prevent the bearing from damaging its seat. Any damage to the housing seat can restrict axial movement or prohibit it

entirely over time. This is particularly important if the housing is made of a light alloy.

If needle roller bearings, CARB toroidal roller bearings or cylindrical roller bearings without flanges on one ring are used, both bearing rings can be mounted with an interference fit, because axial displacement can take place internally, within the bearing.

### Bearings with a tapered bore

Bearings with a tapered bore can be mounted directly on tapered shaft seats, or on adapter or withdrawal sleeves (→ **figs. 25 to 28, page 207**). Sleeves that are fitted to cylindrical shaft seats have an external taper. Whether the bearing is mounted on a sleeve or directly on the shaft, the fit of the bearing inner ring is not pre-determined by the bearing seat, as is the case for bearings with a cylindrical bore. Instead, the fit for bearings with a tapered bore is determined by the distance through which the ring is driven up on its tapered seat or on the sleeve. Special precautions relative to the internal clearance reduction must be considered as mentioned under *Bearing clearance* (→ **page 213**) and under *Self-aligning ball bearings* (→ **page 537**), *Spherical roller bearings* (→ **page 879**), and *CARB toroidal roller bearings* (→ **page 957**).

If the bearings are to be mounted on an adapter or withdrawal sleeve, larger diameter tolerances are permitted for the sleeve seat, but the tolerances for total radial run-out must be tighter (→ *Dimensional and geometrical tolerances of bearing seats and abutments, page 200*).

### Recommended fits

The tolerances for the bore and outside diameter of rolling bearings are standardized internationally (→ *Tolerances, page 132*).

To achieve an interference or loose fit for metric bearings with a cylindrical bore and outside surface, suitable tolerance classes for the bearing seat on the shaft and in the housing bore are selected from the ISO tolerance system. Only a limited number of ISO tolerance classes need be considered for the shaft and housing seats for rolling bearings. The location of the most commonly used tolerance classes relative to the bearing bore and outside diameter surface are shown in **fig. 17, page 170** (valid for bearings with Normal tolerances).

Each ISO tolerance class is identified by a letter and a number. The letter, lower case for shaft diameters and upper case for housing bores, locates the tolerance zone relative to the nominal dimension. The number indicates the range of the tolerance zone. The higher the number, the larger the tolerance zone.

Recommendations for bearing fits for solid steel shafts are provided in the tables referenced in the following:

- radial bearings with a cylindrical bore (→ **table 2, page 172**)
- thrust bearings (→ **table 3, page 174**)

Recommendations for bearing fits for cast iron and steel housings are provided in the tables referenced in the following:

- radial bearings – non-split housings (→ **table 4, page 174**)
- radial bearings – split or non-split housings (→ **table 5, page 175**)
- thrust bearings (→ **table 6, page 175**)

These recommendations are based on the general selection guidelines described above, which take developments in bearing and housing materials, design and manufacturing into account. Modern bearings and housings can accommodate substantially heavier loads than was previously possible. The recommendations in this catalogue reflect these improvements.

**NOTE:** All ISO tolerance classes are valid with the envelope requirement (such as H7<sup>Ⓔ</sup>) in accordance with ISO 14405-1. For practical reasons, this is not indicated in the following tables.

ISO 14405-1 offers more possibilities to specify fits. For additional information, contact the SKF application engineering service.

## Design considerations

### Stainless steel bearings or shafts

The recommended fits in **tables 2 to 6** (→ **pages 172 to 175**) can be used for stainless steel bearings. However, footnote 3 in **table 2** (→ **page 172**) does not apply, because stainless steel has a much higher coefficient of thermal expansion than standard steel. If tighter fits than those recommended in **table 2** (→ **page 172**) are needed, contact the SKF application engineering service. It may also be necessary to consider the initial bearing clearance, such as when using stainless steel shafts at elevated temperatures (→ *Bearing internal clearance*, **page 149**).

### Shaft and housing tolerances and fits

The values listed for the shaft (→ **tables 7, page 178**) and housing (→ **tables 8, page 190**) tolerances enable the character of the fit to be established:

- the upper and lower limits of Normal tolerances for the bearing bore or outside diameter deviations
- the upper and lower limits of the shaft or housing bore diameter deviations in accordance with ISO 286-2

Normal tolerances for the bore and outside diameter, for which the limiting values have been calculated, are valid for all metric rolling bearings except for metric tapered roller bearings when  $d \leq 30$  mm or  $D \leq 150$  mm and thrust bearings when  $D \leq 150$  mm. The diameter tolerances for these bearings deviate from the Normal tolerances for other rolling bearings (→ **tables 3 to 10, pages 137 to 144**).

The values for the probable interference or loose fit cover 99% of all the combinations.

When bearings with higher dimensional accuracy than Normal are used, the bore and outside diameter tolerances are tighter. Therefore, values for an interference or loose fit need to be adjusted correspondingly. For information about calculating these limits more accurately, contact the SKF application engineering service.

**NOTE:** The signs for clearance and interference in this catalogue are in accordance with ISO 286-1. Clearance is now indicated with a "+" sign and interference with a "-" sign.

## Design considerations

### Fits for solid steel shafts

#### Radial bearings with a cylindrical bore<sup>1)</sup>

##### Conditions

##### Examples

#### Rotating inner ring load or direction of load indeterminate

Light and variable loads ( $P \leq 0,05 C$ )

Conveyors, lightly loaded gearbox bearings

Normal to heavy loads ( $P > 0,05 C$ )

General bearing applications, electric motors, turbines, pumps, gearing, wood-working machines

Heavy to very heavy loads and shock loads under difficult operating conditions ( $P > 0,1 C$ )

Axleboxes for heavy railway vehicles, traction motors, rolling mills, wind turbines

High demands on running accuracy with light loads ( $P \leq 0,05 C$ )<sup>2)</sup>

Machine tools (precision class bearings)

#### Stationary inner ring load

Easy axial displacement of inner ring on shaft desirable

Wheels on non-rotating axles

Easy axial displacement of inner ring on shaft unnecessary

Tension pulleys, rope sheaves

#### Axial loads only

Bearing applications of all kinds

<sup>1)</sup> For needle roller bearings → *Needle roller bearings*, page 673. For Y-bearings → *Y-bearings*, page 421.

<sup>2)</sup> All ISO tolerance classes are valid with the envelope requirement (such as H7(E)) in accordance with ISO 14405-1.

<sup>3)</sup> Ball bearings under normal to heavy loads ( $P > 0,05 C$ ) often require radial internal clearance greater than Normal when the shaft tolerance classes listed above are used. If radial clearance is greater than Normal, but the operating conditions require tighter fits to prevent the inner ring from creeping, use the following tolerance classes:

- k4(E) for shaft diameters 10 to 17 mm
- n6(E) for shaft diameters > 140 to 300 mm
- k5(E) for shaft diameters > 17 to 25 mm
- p6(E) for shaft diameters > 300 to 500 mm
- m5(E) for shaft diameters > 25 to 140 mm

For additional information, contact the SKF application engineering service.

The recommendations provided under this footnote are not valid for stainless steel bearings.

<sup>4)</sup> The tolerance in brackets applies to stainless steel bearings.

<sup>5)</sup> For stainless steel bearings within the diameter range 17 to 30 mm, tolerance class j5(E) applies.

## Design considerations

### Fits for hollow shafts

If bearings are to be mounted with an interference fit on a hollow shaft, to achieve the same surface pressure between the inner ring and shaft seat, it is generally necessary to use a tighter interference fit than would be used for a solid shaft. The following diameter ratios are important when deciding on the fit to be used:

$$c_i = \frac{d_i}{d} \quad \text{and} \quad c_e = \frac{d}{d_e}$$

The fit is not appreciably affected until the diameter ratio of the hollow shaft  $c_i \geq 0,5$ .

If the average outside diameter of the inner ring, i.e. the average diameter between the shoulder and raceway ( $\rightarrow$  **diagram 1**), is not known, the diameter ratio  $c_e$  can be estimated with sufficient accuracy using

$$c_e = \frac{d}{k(D - d) + d}$$

where

$c_i$  = diameter ratio of the hollow shaft

$c_e$  = diameter ratio of the inner ring

$d$  = outside diameter of the hollow shaft, bearing bore diameter [mm]

$D$  = bearing outside diameter [mm]

$d_i$  = inside diameter of the hollow shaft [mm]

$d_e$  = average outside diameter of the inner ring [mm] ( $\rightarrow$  **diagram 1**)

$k$  = a factor for the bearing type

– for self-aligning ball bearings in the 22 and 23 series,  $k = 0,25$

– for cylindrical roller bearings,  $k = 0,25$

– for all other bearings,  $k = 0,3$

The requisite interference fit for a bearing mounted on a hollow shaft can be determined based on the mean probable interference for the same bearing on a solid shaft, neglecting plastic deformation (smoothing) of the mating surfaces produced during mounting. The mean probable interference for the bearing on a solid shaft,  $\Delta_S$ , is the mean value of the smallest and largest values of the probable interference listed in **table 7** ( $\rightarrow$  **page 178**).

**Diagram 1** provides values for the ratio between the mean probable interference of the bearing inner ring on a hollow shaft,  $\Delta_H$ , and

on a solid shaft,  $\Delta_S$ , depending on the diameter ratios  $c_i$  and  $c_e$ .

#### Example

A 6208 deep groove ball bearing with  $d = 40$  mm and  $D = 80$  mm is to be mounted on a hollow shaft with a diameter ratio  $c_i = 0,8$ . What is the requisite interference and what are the appropriate shaft limits?

If the bearing is to be mounted on a solid steel shaft and subjected to normal loads, a tolerance class k5 (E) is recommended. From **table 7d** ( $\rightarrow$  **page 184**), for a 40 mm shaft diameter, the mean probable interference  $\Delta_V = (22 + 5) / 2 = 13,5$   $\mu\text{m}$ . For  $c_i = 0,8$  and

$$c_e = \frac{40}{0,3(80 - 40) + 40} = 0,77$$

so that from **diagram 1** the ratio  $\Delta_H / \Delta_S = 1,7$ . Therefore, the requisite interference for the hollow shaft  $\Delta_H = 1,7 \times 13,5 = 23$   $\mu\text{m}$ . Consequently, tolerance class m6 (E) is selected for the hollow shaft as this gives a similar fit as k5 (E) for a solid shaft.

## Design considerations

### Dimensional and geometrical tolerances of bearing seats and abutments

The tolerances for cylindrical bearing seats on shafts and in housings and the seats for thrust bearing washers and for their support surfaces (abutments for bearings provided by shaft and housing shoulders etc.) should correspond to the tolerance class of the bearings. Guideline values for the dimensional and geometrical tolerances are provided hereafter.

#### Dimensional tolerances

For bearings made to Normal tolerances, the dimensional tolerances for cylindrical seats should be, at the very minimum, IT6 grade for the shaft and IT7 for the housing. Where adapter or withdrawal sleeves are used, wider diameter tolerances (IT9 grade) can be permitted for shaft seats (→ **table 9**). The numerical values of standard IT tolerance grades in accordance with ISO 286-1 are listed in **table 10**. For bearings with higher dimensional accuracy, correspondingly tighter grades should be used.

#### Tolerances for total radial run-out

Depending on the application requirements, the total radial run-out tolerances as defined in ISO 1101 should be one to two IT grades tighter than the prescribed dimensional tolerance. For example, if the specifications require a shaft seat in accordance with a tolerance class m6<sup>Ⓔ</sup>, the total radial run-out should be IT5 or IT4. The tolerance value  $t_3$  for total radial run-out is obtained for an assumed shaft diameter of 150 mm from  $t_3 = IT5/2 = 18/2 = 9 \mu\text{m}$ . Guideline values for the tolerances for total radial run-out are listed in **table 11** (→ **page 202**).

When bearings are to be mounted on adapter or withdrawal sleeves, the total radial run-out of the sleeve seat should be IT5/2 for tolerance class h9<sup>Ⓔ</sup> (→ **table 9**).

#### Tolerances for total axial run-out

Abutments for bearing rings should have a total axial run-out tolerance as defined in ISO 1101, which is better by at least one IT grade than the diameter tolerance of the associated cylindrical seat. For thrust bearing washer seats, the tolerance for total axial run-out should not exceed IT5. Guideline values for the tolerances for total axial run-out are listed in **table 11** (→ **page 202**).

## Design considerations

### Tolerances for tapered shaft seats

When a bearing is mounted directly onto a tapered shaft seat, the tolerance grade of the diameter of the shaft seat can be wider than the tolerance grade for a cylindrical seat.

**Fig. 18** shows an IT9 grade diameter tolerance, while the stipulated geometrical tolerance is the same as for a cylindrical shaft seat. For rolling bearings mounted on tapered shaft seats, SKF recommends:

- The permissible deviation for the slope of the taper should be a  $\pm$  tolerance in accordance with IT7/2, and is based on the bearing width B ( $\rightarrow$  **fig. 18**). For design purposes, the tolerance value has to be expressed in degrees. The value can be determined using

$$\Delta_k = \frac{IT7/2}{B}$$

Table 11

<b>Explanation</b>

	For special demands with respect to running accuracy or even support					

<sup>1)</sup> For bearings with a tolerance class higher than Normal (tolerance class P4 etc.), refer to *Super-precision bearings* ( $\rightarrow$  [skf.com/super-precision](http://skf.com/super-precision)).

The permissible deviation for the slope of the taper can be determined using

$$V_k = 1/k \pm \frac{IT7/2}{B}$$

where

$\Delta_k$  = the permissible deviation of the slope of the taper

$V_k$  = the permissible range of dispersion of the slope of the taper

$B$  = bearing width [mm]

IT7 = the value of the tolerance grade, based on the bearing width [mm]

$k$  = factor for the taper

– for taper 1:12,  $k = 12$

– for taper 1:30,  $k = 30$

- The straightness tolerance grade IT5/2, based on the diameter  $d$ , is defined as: “In each axial plane through the tapered surface of the shaft, the tolerance zone is limited by two parallel lines a distance “ $t$ ” apart.”

- The circularity tolerance grade IT5/2, based on the diameter  $d$ , is defined as distance “ $t$ ” in each radial plane between two concentric circles along the tapered surface of the shaft. In applications where a high degree of running accuracy is required, IT4/2 should be used instead.

Only dimensional and geometrical tolerances of the taper are indicated in **fig. 18**. To locate the taper axially, individual specifications have to be provided.

To check whether a shaft taper is within its recommended tolerances, SKF recommends measuring it with a special taper gauge, based on two saddles. More practical, but less accurate measurement methods include ring gauges, taper gauges and sine bars. For information about SKF measuring devices such as RKM, 9205, GRA 30 series ring gauges and DMB taper gauges, contact the SKF application engineering service.

<sup>1)</sup> For diameters > 1 250 mm, contact the SKF application engineering service.  
<sup>2)</sup> When using the oil injection method for mounting,  $R_a$  should not exceed 1,6 μm.

### Surface roughness of bearing seats

The surface roughness of a bearing seat does not have the same degree of influence on bearing performance as the dimensional and geometrical tolerances of the seat. However, obtaining a desired interference fit depends on the roughness of the mating surfaces, which is directly proportional to fit accuracy. For less critical bearing arrangements a relatively rough surface finish is permitted.

Guideline values for the mean surface roughness  $R_a$  are listed in **table 12** for different bearing seat tolerance grades. These recommendations apply to ground seats, which are normally assumed for shaft seats.

### Axial location of bearings

In general, an interference fit alone is inadequate to locate a bearing ring on a cylindrical seat. Under load and deflection, a bearing ring can wander on its seat. Some suitable means to secure the bearing axially are needed.

For a locating bearing, both rings should be secured axially on both sides.

For a non-separable bearing in the non-locating position, the ring with an interference fit, typically the inner ring, should be secured axially on both sides. The other ring must be free to move axially on its seat to accommodate axial displacement.

For non-locating bearings, CARB, cylindrical and needle roller bearings are exceptions. The inner and outer rings of these bearings must be secured axially in both directions.

For a cross-locating bearing system, each bearing ring needs to be secured axially on one side only.

## Locating methods

### Bearings with a cylindrical bore

Bearing rings that are mounted with an interference fit typically have one ring that abuts a shoulder on the shaft (→ **fig. 19**) or in the housing. On the opposite side, the inner ring is normally secured by a KM lock nut with an MB lock washer attached to the shaft end (→ **fig. 19**) or an end plate (→ **fig. 20**). Outer rings are typically located by a housing cover (→ **fig. 21**) or a threaded ring (→ **fig. 22**).

Fig. 20

Fig. 21

Fig. 19

Fig. 22

## Design considerations

Instead of integral shaft or housing shoulders, spacer sleeves or collars can be used between the bearing rings or between a bearing ring and an adjacent component, such as a gear (→ **fig. 23**).

The use of snap rings to locate rolling bearings axially, saves space, enables fast mounting and dismounting, and simplifies the machining of shafts and housing bores. If normal or heavy axial loads have to be supported, an abutment collar should be inserted between the bearing ring and snap ring, so that the snap ring is not subjected to excessive bending moments (→ **fig. 24**). The usual axial play between the snap ring and snap ring groove can be reduced, if necessary, by choosing suitable tolerances for the abutment collar or by using shims.

Another way to locate a bearing axially, which is typically found in super-precision bearing applications, is to use a stepped sleeve with a tight interference fit on the shaft. For detailed information, refer to *Super-precision bearings* (→ [skf.com/super-precision](http://skf.com/super-precision)).

Fig. 23

Fig. 24

### Bearings with a tapered bore

Bearings with a tapered bore, mounted directly on a tapered shaft seat, are typically located axially on the shaft by a lock nut (→ **fig. 25**).

When using an adapter sleeve on a stepped shaft, an L-shaped spacer ring, not supplied by SKF, is fitted between the shaft shoulder and inner ring on one side. A lock nut locates the bearing relative to the sleeve on the opposite side (→ **fig. 26**). Where plain shafts without integral abutments are used (→ **fig. 27**), the friction between the shaft and sleeve governs the axial load carrying capacity of the bearing (→ *Self-aligning ball bearings*, **page 537** and *Spherical roller bearings*, **page 879**).

When bearings are mounted on withdrawal sleeves, an abutment, such as a spacer ring, which is frequently designed as a labyrinth ring, must support the inner ring. The withdrawal sleeve is located axially by an end plate or lock nut (→ **fig. 28**).

Fig. 26

Fig. 27

Fig. 25

Fig. 28

## Design considerations

### Abutment and fillet dimensions

The dimensions of components adjacent to a bearing (such as shaft and housing shoulders, spacer sleeves) must be able to provide sufficient support for the bearing rings. However, there must not be any contact between the rotating parts of the bearing and a stationary adjacent component. Appropriate abutment and fillet dimensions are listed in the product tables.

The transition between the bearing seat and shaft or housing shoulder can be a fillet in accordance with the dimensions  $r_a$  and  $r_b$  in the product tables, or an undercut ( $\rightarrow$  table 13). As the fillet radius increases, the stress distribution in the fillet area improves. Therefore, heavily loaded shafts, which typically require a larger radius, use a spacing collar between the inner ring and shaft shoulder to provide a sufficiently large support surface for the bearing ring. The side of the collar that abuts the shaft shoulder should be designed so that it does not contact the fillet ( $\rightarrow$  fig. 29).

**CARB toroidal roller bearings**

CARB toroidal roller bearings can accommodate axial displacement of the shaft within the bearing. To be sure that displacement of the shaft relative to the housing can occur, sufficient space  $C_a$  must be provided on both sides of the bearing (→ **fig. 30**).

For additional information, refer to *CARB toroidal roller bearings* (→ **page 957**).

Fig. 30

## Design of associated components

### Raceways on shafts and in housings

If the load carrying capacity of a bearing or assembly is to be fully exploited, the raceways machined in associated components for cylindrical and needle roller bearings with only one ring, must have a hardness between 58 and 64 HRC. The surface roughness should be  $R_a \leq 0,2 \mu\text{m}$  or  $R_z \leq 1 \mu\text{m}$ . For less demanding applications, lower hardness and rougher surfaces may be used.

Roundness should be within 25% and the total radial run-out tolerance should be within 50% of the actual diameter tolerance range of the raceway.

The permissible axial run-out of the raceways for thrust assemblies are the same as for the shaft and housing washers of thrust bearings (→ **table 10, page 144**).

Suitable materials for the raceways include steels for through-hardening, such as 100Cr6 in accordance with ISO 683-17, steels for case-hardening, such as 20Cr3 or 17MnCr5 in accordance with ISO 683-17, as well as steels for induction-hardening that can be partially hardened.

The recommended case depth for raceways machined in associated components depends on various factors, including the dynamic and static load ratios ( $P/C$  and  $P_0/C_0$  respectively) as well as the core hardness, which makes it difficult to generalize. For example, when core hardness is 350 HV, the recommended case depth is generally 0,1 times the rolling element diameter for purely static loads less than or equal to the basic static load rating. Shallower case depths are permitted for dynamic loads.

For additional information, contact the SKF application engineering service.

### Provisions for mounting and dismounting

Particularly when large bearings are involved, SKF recommends making provisions during the design stage to facilitate mounting and dismounting. If, for example, slots or recesses are machined in the shaft and/or housing shoulders, it is possible to apply withdrawal tools (→ **fig. 31**). Threaded holes in the housing shoulders also enable the use of bolts to push or pull the bearing from its seat (→ **fig. 32**).

If the oil injection method is to be used to mount or dismount bearings on a tapered seat, or to dismount bearings from a cylindrical seat, ducts and grooves should be provided in the shaft (→ **fig. 33**). Recommended dimensions for the appropriate grooves, ducts and threaded holes to connect the oil supply are listed in **tables 14 and 15**.

## Selecting internal clearance or preload

The operating clearance or preload in a bearing is determined by:

- the initial internal clearance prior to mounting
- the actual fits
- the effects of form errors
- the internal clearance or preload built into the bearing after mounting
- the dimensional changes resulting from the operating temperature

Shaft deflection and axial displacement, such as in CARB toroidal roller bearings, might also need to be considered.

The operating clearance or preload in a bearing influences friction, size of the load zone and fatigue life. **Diagram 2** shows the relationship between clearance and preload, and the primary parameters. The diagram is based on rolling bearings under radial load.

Clearance and preload versus performance of primary parameters

## Clearance versus preload

For most applications, bearings operate with some residual clearance. Normally, a positive operating clearance near zero is the optimum (→ **diagram 2**).

A somewhat greater clearance may be more suitable for:

- high-speed applications to reduce frictional heat
- form errors on the shaft or housing seat such as ovality

The initial internal clearance prior to mounting and permissible reduction after mounting, depend on the type and size of the bearing. The reduction in clearance due to an interference fit may require greater initial internal clearance than Normal to avoid preloading the bearing (→ **fig. 15, page 167**).

Preload (negative operating clearance) has advantages, but can also be risky. If a high degree of stiffness is required, light preload can be suitable (→ *Bearing preload*, **page 214**).

A light preload may also be required when there is a very light or no external load on the bearing in operation.

In this case, however, there is a risk that too much preload causes the bearing to overheat, which further increases preload, friction and heat. This cycle can continue until the bearing seizes.

It could be argued that preload is acceptable, provided the bearing operates in a zone that does not exceed light preload (→ **diagram 2**, zone between 0 and -1). In this case, however, there is an increase in friction and frictional heat.

Although all bearing types can run with some preload, SKF recommends a positive operating clearance. This is particularly important for roller bearings such as cylindrical roller, needle roller, spherical roller and CARB toroidal roller bearings.

## Bearing clearance

### Selecting a clearance class

The clearance values listed in the relevant product chapters are valid for unmounted bearings. To select the best clearance value for an application, the required operating clearance in the bearing (in operation) must be determined first.

Because there are many factors that can influence operating clearance in a bearing, these calculations are best done with the aid of sophisticated computer programs. As a result, SKF recommends using one of the computer programs available through the SKF application engineering service. These programs consider tolerances, fits and component temperatures, to calculate the required initial internal clearance.

The required initial internal clearance of an unmounted bearing can be estimated using

$$r = r_{op} + \Delta r_{fit} + \Delta r_{temp}$$

where

$r$  = required initial internal clearance for the unmounted bearing [mm]

$r_{op}$  = desired operating clearance [mm]

$\Delta r_{fit}$  = clearance reduction caused by the fit [mm]

$\Delta r_{temp}$  = clearance reduction caused by temperature difference [mm]

### Clearance reduction caused by an interference fit

The reduction equals the effective interference fit multiplied by a reduction factor using

$$\Delta r_{fit} = \Delta_1 f_1 + \Delta_2 f_2$$

where

$\Delta r_{fit}$  = clearance reduction caused by the fit [mm]

$f_1$  = reduction factor for the inner ring

$f_2$  = reduction factor for the outer ring

$\Delta_1$  = effective interference between the inner ring and shaft [mm]

$\Delta_2$  = effective interference between the outer ring and housing [mm]

## Design considerations

The reduction factors can be obtained from **diagram 3** as a function of the ratio of the bearing bore diameter  $d$  to the outside diameter  $D$ . It is valid for a solid steel shaft and a cast iron or steel housing. For the effective interference fit, the mean value of the smallest and largest values of the probable interference listed in **table 7** (→ **page 178**) and **table 8** (→ **page 190**) can be used.

### Clearance reduction caused by a temperature difference between the bearing rings

When the inner ring temperature is higher than the outer ring temperature, the internal clearance within the bearing is reduced. The internal clearance reduction can be estimated using

$$\Delta r_{\text{temp}} = \alpha d_m \Delta T$$

where

$\Delta r_{\text{temp}}$  = clearance reduction caused by temperature difference [mm]

$d_m$  = bearing mean diameter [mm]  
=  $0,5 (d + D)$

$\alpha$  = thermal coefficient of expansion [ $^{\circ}\text{C}^{-1}$ ]  
for steel,  $\alpha = 12 \times 10^{-6}$

$\Delta T$  = temperature difference between the shaft and housing [ $^{\circ}\text{C}$ ]

The temperature difference between components during start-up can be much higher than under steady state conditions (→ **diagram 4**) and unwanted preload may result. It is important to avoid unwanted preload during start-up, because even short periods of preload can have a negative impact on bearing service life. One way to avoid excessive heat and the resulting preload is to start the application at a slow speed and increase the speed incrementally.

## Bearing preload

Depending on the applications, there might be a need to preload the bearing arrangement i.e. apply a negative operating clearance.

In applications like machine tool spindles, automotive differentials and electric motors, where preload enhances stiffness or running accuracy, SKF recommends applying preload with springs if an adjustment nut is not available. Springs should also be used under very

Diagram 3

Factors  $f_1$  and  $f_2$  for clearance reduction caused by interference fits

Diagram 4

Temperature differences during start-up

Fig. 34

light or no-load conditions to provide a minimum load on the bearing (→ *Requisite minimum load*, page 86).

Preload can be expressed as a force or as a distance (path), but is typically expressed as a force.

Depending on the adjustment method, preload is also indirectly related to the frictional moment in the bearing.

Empirical preload values can be obtained from proven designs and can be applied to similar designs. For new designs, SKF recommends calculating the preload force and checking its accuracy by testing the application. In general, all influencing factors in operation cannot be fully identified in the design stage and adjustments may be necessary. The accuracy of the calculation depends on how closely the estimated operating temperature and elastic behaviour of the associated components – most importantly the housing – coincide with the actual conditions in operation.

### Considerations for preload

Depending on the bearing type, preload may be either radial or axial. Cylindrical roller bearings, for example, can only be preloaded radially because of their design, while thrust ball and cylindrical roller thrust bearings can only be preloaded axially. Single row angular contact ball bearings and tapered roller bearings (→ fig. 34), which are normally subjected to axial preload, are generally mounted together with a second bearing of the same type and size in a back-to-back (load lines diverge) or face-to-face (load lines converge) arrangement. Deep groove ball bearings can also be preloaded axially. If so, the bearings should have a greater radial internal clearance than Normal (such as C3) so that, as with angular contact ball bearings, a contact angle that is greater than zero is obtained.

Back-to-back arrangement

Face-to-face arrangement

F

## Design considerations

For both tapered roller and angular contact ball bearings, the distance  $L$  between the pressure centres is longer when the bearings are arranged back-to-back (→ fig. 35) compared to bearings that are arranged face-to-face (→ fig. 36). This means that bearings arranged back-to-back can accommodate relatively large tilting moments even if the distance between the bearing centres is relatively short. The radial loads and bearing deformation resulting from a moment load is smaller for bearings arranged back-to-back than for bearings arranged face-to-face.

If in operation the shaft temperature is higher than the housing temperature, the preload, which was adjusted at ambient temperature during mounting, increases. The in-

crease is greater for bearings arranged face-to-face than for bearings arranged back-to-back. In both cases, however, thermal expansion of the inner ring in the radial direction serves to reduce clearance or increase preload. This tendency is increased by thermal expansion of the rings in the axial direction when the bearings are face-to-face, but is reduced for back-to-back arrangements.

For back-to-back arrangements only: Depending on the distance between the bearings, when the coefficient of thermal expansion is the same for the bearings and associated components, thermal expansion in both the radial and axial directions can cancel each other out so that preload remains unchanged.

Fig. 35

### Back-to-back arrangements

Fig. 36

### Face-to-face arrangements

### Effects of bearing preload

The primary benefits resulting from preload include but are not limited to:

- enhanced stiffness
- reduced noise levels
- improved shaft guidance
- compensation for wear and settling
- extended bearing service life

#### Enhanced stiffness

Bearing stiffness [kN/mm] is defined as the ratio of the force acting on the bearing to the elastic deformation in the bearing. The elastic deformation caused by a load in preloaded bearings is smaller for a given load range than for bearings that are not preloaded.

#### Reduced noise levels

As operating clearance in a bearing decreases, guidance of the rolling elements in the unloaded zone improves, which reduces noise levels in operation.

#### Improved shaft guidance

Preloaded bearings provide more accurate shaft guidance because preload provides a higher degree of stiffness, which limits the ability of the shaft to deflect under load. For example, preloading the ring and pinion bearings in a differential results in increased stiffness, which keeps gear mesh accurate and constant. This minimizes dynamic forces and reduces noise levels, which can extend the service life of the gears.

#### Compensation for wear and settling

Wear and settling in a bearing arrangement in operation increases the clearance. This clearance can be compensated for with preload.

#### Extended bearing service life

In certain applications, an optimum preloaded bearing system (→ *Selecting the correct preload*, page 225) can enhance operational reliability, provide more favourable load distribution in the bearings and extend bearing service life.

## Design considerations

### Preload in bearing systems with angular contact ball or tapered roller bearings

When determining preload, the preload force required to provide an optimum combination of stiffness, bearing service life and operational reliability should be calculated first. Then calculate the preload force to be used when adjusting the bearings during mounting. When mounting, the bearings should be at ambient temperature and should not be subjected to any other load.

The appropriate preload at normal operating temperature depends on the bearing load. An angular contact ball bearing or a tapered roller bearing can accommodate radial and axial loads simultaneously. Under radial load, these bearings produce a resultant axial load which must be accommodated by a second bearing facing the opposite direction. Purely radial displacement of one bearing ring relative to the other means that half of the rolling elements are under load. The resultant axial load produced in the bearing can be determined by:

- for single row angular contact ball bearings  
 $F_a = R F_r$
- for single row tapered roller bearings  
 $F_a = 0,5 F_r / Y$

where

$F_a$  = axial bearing load (→ fig. 37)

$F_r$  = radial bearing load (→ fig. 37)

$R$  = variable for inside contact conditions

(→ *Calculating the axial load for bearings mounted singly or paired in tandem*, page 495)

$Y$  = calculation factor (→ **product tables**)

When a single bearing is subjected to a radial load  $F_r$ , an axial load  $F_a$  (external) of the same magnitude as the resultant load must be applied to the bearing if the basic load rating is to be fully exploited. If the applied external load is lighter, there are fewer rolling elements supporting the load and the load carrying capacity of the bearing is correspondingly reduced.

In a bearing system consisting of two single row angular contact ball bearings or two tapered roller bearings arranged back-to-back or face-to-face, each bearing arrangement must accommodate the axial load in one direction. When these bearing systems are adjusted to near-zero clearance, the radial load is shared equally between the two bearings and half the rolling elements in each bearing are loaded.

In other cases, where there is an external axial load, it may be necessary to preload the bearings to compensate for the clearance that can occur when the axially loaded bearing deforms elastically. Preload also distributes the loads more favourably in an axially unloaded bearing.

Fig. 37

Preload also increases the stiffness of a bearing system. However, keep in mind that stiffness is also influenced by the elasticity of the shaft and housing, the shaft and housing fits, as well as the elastic deformation of all other components adjacent to the bearings, including the abutments. Each of these has a considerable impact on the resilience of the total bearing system. The axial and radial resilienties of a bearing depend on its internal design, contact conditions (point or line contact), the number and diameter of rolling elements and the contact angle. The greater the contact angle, the higher the degree of stiffness in the axial direction.

If, as a first approximation, a linear dependence of the resilience on the load is assumed, such as a constant spring ratio, a comparison shows that the axial displacement in a bearing system under preload is smaller than for a bearing system without preload for the same external axial force  $K_a$  (→ **diagram 5**). A pinion arrangement design (→ **figs. 39 and 40, page 222**) typically consists of two different size tapered roller bearings, A and B, with different spring constants  $c_A$  and  $c_B$ . Both are subjected to a preload force  $F_0$ . If an axial force  $K_a$  acts on bearing A, bearing B becomes unloaded, and the additional load acting on bear-

ing A results in an axial displacement  $\delta_a$  that is smaller than it would be if the bearings had not been preloaded. However, B is relieved of the axial preload force and the axial displacement under additional load is the same as it is for a bearing system without preload, that means determined solely by the spring constant  $c_A$ , if the external axial force exceeds the value

$$K_a = F_0 \left( 1 + \frac{c_A}{c_B} \right)$$

To prevent bearing B from becoming unloaded when bearing A is subjected to an axial force  $K_a$ , the following preload force is required

$$F_0 = K_a \left( \frac{c_B}{c_A + c_B} \right)$$

Diagram 5

Axial displacement in bearing systems with and without preload

F

## Design considerations

Loads and elastic displacements in a preloaded bearing system, as well as the effects of a change in preload, are easily understood from a preload force / axial displacement diagram (→ **diagram 6**). This consists of the spring curves of the components that are adjusted against each other to apply preload and enables the following:

- the relationship of the preload force and axial displacement within the preloaded bearing system
- the relationship between an externally applied axial force  $K_a$  and the bearing load for a preloaded bearing system, as well as the elastic deformation produced by an external load

In **diagram 6**, all the components subjected to external loads in operation are represented by the curves that increase from left to right, and all the unloaded components by the curves that increase from right to left. Curves 1, 2 and 3 are for different preload forces ( $F_{01}$ ,  $F_{02} < F_{01}$  and  $F_{03} = 0$ ). The broken lines represent individual bearings, while the solid lines represent the total bearing system (bearing(s) and associated components) for different preload forces.

From **diagram 6**, it is also possible to explain the relationship between components, for example in a pinion arrangement design (→ **fig. 39, page 222**), where bearing A is located adjacent to a gear and is adjusted against bearing B to provide preload. The external axial force  $K_a$  (axial component of tooth forces) is superimposed on the preload force  $F_{01}$  (curve 1) in such a way that bearing A is subjected to additional load while bearing B is unloaded. The load on bearing A is designated  $F_{aA}$  and on bearing B it is designated  $F_{aB}$ . Under the influence of the axial force  $K_a$ , the pinion shaft is axially displaced by the amount  $\delta_{a1}$ .

The smaller preload force  $F_{02}$  (curve 2) has been chosen so that bearing B is just unloaded by the axial force  $K_a$ , that means  $F_{aB} = 0$  and  $F_{aA} = K_a$ . The pinion shaft is displaced in this case by the amount  $\delta_{a2} > \delta_{a1}$ .

When the arrangement is not preloaded (curve 3), the axial displacement of the pinion shaft is greatest ( $\delta_{a3} > \delta_{a2}$ ).

Diagram 6

### Influence of preload and axial load on axial displacement in bearing systems

## Adjustment procedures

Adjustment means setting the bearing internal clearance (→ *Mounting*, page 275) or preload in a bearing system.

The radial preload typically used for cylindrical roller bearings, double row angular contact ball bearings and sometimes for deep groove ball bearings, for example, is achieved by an interference fit on one or both bearing rings. The degree of interference should reduce residual clearance to zero, which is further reduced to a negative clearance (preload) when the bearing is in operation.

Bearings with a tapered bore are particularly suitable for radial preloading since, by driving the bearing up onto its tapered seat, the preload can be applied to within narrow limits.

Axial preload in a bearing system with single row angular contact ball bearings, tapered roller bearings and deep groove ball bearings is produced by displacing one bearing ring axially, relative to the other, by an amount corresponding to the desired preload force. There are basically two principal methods to adjust preload: individual adjustment and collective adjustment.

### Individual adjustment

With individual adjustment, each bearing system is adjusted separately using nuts, shims, spacer sleeves, crush sleeves etc. Measuring and inspection procedures provide that the established nominal preload is obtained with the least possible deviation. There are different methods to obtain the required preload:

- axial displacement method
- frictional moment method
- direct force method

The method used depends on, among other things, the application design and the number of bearings to be mounted. Individual adjustment can accommodate enough tolerance stack-up so that if individual components are produced to Normal tolerances, the desired preload can be achieved with a relatively high degree of accuracy.

Fig. 38

Fig. 39

Fig. 40

**Axial displacement method**

The axial displacement method is based on the relationship between the preload force and the elastic deformations within the bearing system. The requisite preload can be determined from a preload force / axial displacement diagram (→ **diagram 7**).

This method of adjustment is frequently used when the components of a bearing system are pre-assembled. The required preload, which is expressed as a linear value, requires measuring total axial displacement (end play) of the shaft relative to a fixed surface. This is typically done with a dial indicator.

Shims, intermediate rings or spacers can then be used to adjust axial displacement to the correct value. The preload is achieved, for example, for pinion arrangement designs by:

- fitting intermediate rings between the inner and outer rings of the two bearings (→ **fig. 38**)
- inserting shims between the housing shoulder and the bearing outer ring or between the cartridge and the housing (→ **fig. 39**), where the cartridge in this case is the flanged angled insert

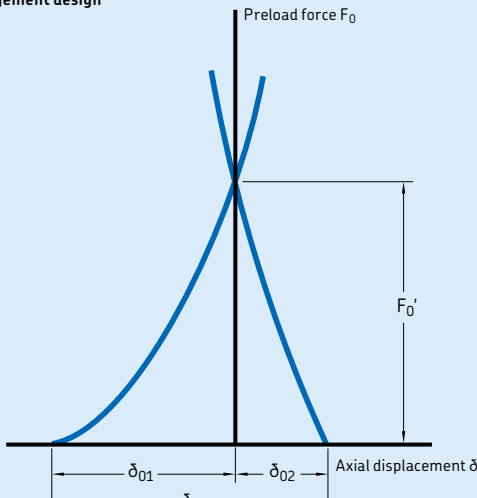

- fitting a spacer between a shaft shoulder and one of the bearing inner rings (→ **fig. 40**) or between the inner rings of both bearings

The width of the shims, intermediate rings or spacers is determined by:

- the distance between the shaft and housing shoulders
- the total width of both bearings
- the axial displacement corresponding to the desired preload force
- a correction factor for the axial displacement to account for thermal expansion in operation
- the manufacturing tolerances of all related components, established by measuring the actual dimensions before mounting
- a correction factor to account for a certain loss of preload as a result of settling and wear

## Design considerations

### Frictional moment method

This method is common in series production because it is fast and can be automated. Since there is a relationship between bearing preload and the frictional moment in the bearings, it is possible to stop adjustment when a frictional moment corresponding to the desired preload has been reached. This can be done if the frictional moment is continuously monitored while setting preload. However, the frictional moment can vary from bearing to bearing, and it also depends on the preservative, the lubricant and the sealing method.

### Direct force method

As the purpose of bearing adjustment is to obtain a specific preload, it would seem sensible to use a method either to produce or to measure the force directly. However, in practice, the indirect methods of adjustment by axial displacement or frictional moment are preferred as they are simple and can be achieved easily and more cost-effectively.

### Collective adjustment

This method can also be referred to as "random statistical adjustment". Using this method, the bearings, shaft, housing, and any other components are manufactured to Normal tolerances. The components, which are considered fully interchangeable, are assembled randomly. Where tapered roller bearings are concerned, this interchangeability also extends to the inner ring assemblies and outer rings. To avoid high machining costs and the use of

precision bearings, it is assumed that given the limiting values of the tolerances, it is statistically improbable that tolerance stack-up occurs. If, however, accurate preload is to be obtained with as little scatter as possible, manufacturing tolerances must be narrowed. The advantage of collective adjustment is that no inspection is required and no extra equipment is needed when mounting the bearings.

### Preloading with springs

By preloading bearings in small electric motors (up to frame size of 132) or similar applications, it is possible to reduce bearing noise levels. The bearing system in this case comprises a single row deep groove ball bearing at each end of the shaft. The simplest method of applying preload is to use a spring or spring package (→ fig. 41). The spring acts on the outer ring of one of the two bearings. This outer ring must be able to be axially displaced. The preload force remains practically constant, even when there is axial displacement of the bearing as a result of thermal elongation. The requisite preload force can be estimated using

$$F = k d$$

where

F = preload force [kN]

d = bearing bore diameter [mm]

k = a factor, → following

Depending on the design of the electric motor, values of between 0,005 and 0,01 are used for

the factor  $k$ . If preload is used primarily to protect the bearing from the damage caused by external vibrations when stationary, then greater preload is required and  $k = 0,02$  should be used.

Spring loading is also a common method of applying preload to angular contact ball bearings in high-speed grinding spindles. The method is not suitable, however, for bearing applications where a high degree of stiffness is required, where the direction of load changes, or where undefined shock loads can occur.

### Selecting the correct preload

When selecting the preload for a bearing system, the degree of stiffness increases marginally once preload exceeds a given optimum value. When exceeding the optimum value, friction and the resulting increase in heat can substantially reduce bearing service life and negate any benefits (→ **diagram 2, page 212**). Excessive preload involves a risk that the operational reliability of a bearing system is compromised. Because of the complexity normally required to calculate an appropriate preload, SKF recommends contacting the SKF application engineering service.

When adjusting preload in a bearing system, it is also important that the established preload value, determined either by calculation or by experience, is attained with the least possible scatter. To reduce scatter when mounting tapered roller bearings, for example, the shaft should be turned several times, if possible, so that the rollers are not skewed and the roller ends are in contact with the guide flange of the inner ring. Turning the shaft also enables the rollers to make full contact with the outer ring and avoids damage to the raceways. When the rollers are not fully settled into position, a much smaller preload than the requisite value results.

### Bearings for preloaded bearing systems

For certain applications, SKF supplies single bearings or matched bearings, which are specifically made to enable simple and reliable adjustment, or which are matched during manufacture so that after mounting, a predetermined preload is obtained. These include:

- tapered roller bearings to CL7C specifications for higher running accuracy, such as automotive differentials (→ *Tapered roller bearings, page 797*)
- universally matchable single row angular contact ball bearings (→ *Angular contact ball bearings, page 475*)
- matched single row tapered roller bearings (→ *Tapered roller bearings, page 797*)
- matched single row deep groove ball bearings (→ *Deep groove ball bearings, page 295*)

## Sealing solutions

All bearing systems include a shaft, bearings, housing(s), lubricant, associated components, and seals. Seals are vital to the cleanliness of the lubricant and the service life of the bearings.

Where seals for rolling bearings are concerned, a distinction is made between seals that are integrated in the bearing and those that are positioned outside the bearing. Bearings that are capped with seals or shields are generally used in bearing systems where an effective external sealing arrangement is not practical due to space or cost reasons, or where these seals or shields are adequate for the operating conditions.

### Seal types

The purpose of a seal is to retain lubricant and prevent any contaminants from entering into a controlled environment. To be effective, a seal should exhibit the following main characteristics:

- flexible enough to compensate for any surface irregularities
- strong enough to withstand operating pressures
- able to accommodate a wide range of operating temperatures
- resistant to common chemicals
- operate with lowest possible friction, frictional heat and wear

There are several basic seal types:

- static seals
- dynamic seals
- non-contact seals
- bellows and membranes

Seals that make contact with stationary surfaces are called static seals. Their effectiveness depends on the radial or axial deformation of their cross section when installed. Gaskets (→ fig. 42) and O-rings (→ fig. 43) are typical examples of static seals.

Seals in contact with sliding surfaces are called dynamic seals and are used to seal passages between machine components that move relative to each other either linearly or

Fig. 42

circumferentially. Dynamic seals are designed to retain lubricant, exclude contaminants, separate different media and withstand differential pressures. There are various types of dynamic seals, including packing or piston rings, which are used for linear or oscillating movements. However, the most common seal is the radial shaft seal (→ fig. 44), which makes contact with both a stationary and rotating component.

Non-contact radial shaft seals form a narrow gap between the stationary seal lip and rotating component. The gap can be arranged axially, radially or in combination. Non-contact seals, which range from simple gap-type seals to multi-stage labyrinths (→ fig. 45), generate almost no friction and, therefore, do not wear.

Bellows and membranes are used to seal components that have limited movement relative to each other.

Because of their importance for bearing applications, the following information deals almost exclusively with contact and non-contact radial shaft seals, their various designs and executions.

Fig. 43

Fig. 44

Fig. 45

## Selecting seal type

Seals for bearing arrangements should provide maximum protection with a minimum amount of friction and wear, even under the most arduous operating conditions. Because bearing performance and service life are so closely tied to the effectiveness and cleanliness of the lubricant, the seal is a key component in a bearing system. For more information on the influence of contaminants on bearing performance, refer to *Selecting bearing size* (→ page 61).

Many factors have to be considered when selecting the most suitable seal for a particular bearing system. They include:

- the lubricant type: oil, grease or other
- the circumferential speed of the seal counterface
- the shaft arrangement: horizontal or vertical
- possible shaft misalignment or deflection
- run-out and concentricity
- available space
- seal friction and the resulting temperature increase
- environmental influences
- cost

Where full application details are available, refer to:

- *Power transmission seals* (→ [skf.com/seals](https://skf.com/seals))
- the product information available online at [skf.com/seals](https://skf.com/seals)

SKF is one of the largest seal manufacturers in the world and can assist in the selection process if little or no experience is available for a given application. For additional information, contact the SKF application engineering service.

## Design considerations

### Non-contact seals

The effectiveness of a non-contact seal depends, in principle, on the sealing action of the narrow gap between the shaft and housing. The gap may be arranged radially, axially or in combination (→ **fig. 46**). These seals can be as simple as a gap-type radial shaft seal or more complex, like a labyrinth seal. In either case, because there is no contact, these seals generate almost no friction and do not wear. They are not easily damaged by solid contaminants and are particularly well suited for high speeds and high temperatures.

### Contact seals

The effectiveness of a contact seal is determined by the amount of pressure available to keep the seal lip in contact with the seal counterface on the shaft. This pressure (→ **fig. 47**) can be produced either by:

- the resilience of the seal, resulting from the elastic properties of the seal material (**a**)
- the designed interference between the seal and its counterface (**b**)
- a tangential force exerted by a garter spring incorporated in the seal (**c**)

Contact seals are generally very reliable.

Their effectiveness, however, depends on the surface finish of the counterface, the condition of the seal lip and the presence of lubricant between the seal lip and counterface. Friction between the seal lip and counterface can generate a significant amount of heat. As a result, these seals have circumferential speed limits. They are also susceptible to mechanical damage as a result of improper mounting, or by solid contaminants. To protect the seal from the damage caused by solid contaminants, a non-contact seal is typically placed in front of a contact seal.

Fig. 46

Fig. 47

## Integral bearing seals

SKF supplies several bearing types capped with a seal or shield on one or both sides. These provide an economic and space-saving solution to many sealing problems. Bearings capped on both sides are supplied already greased and are generally considered maintenance-free. Actual seal designs are described in detail in the relevant product chapter.

## Bearings with shields

Bearings fitted with shields (→ **fig. 48**) are used in applications where the operating conditions are dry and relatively clean. Shields are also used in applications where reduced friction is important due to speed or operating temperature considerations.

Shields form either a narrow gap toward the inner ring shoulder (**a**) or an effective labyrinth with a recess in the inner ring shoulder (**b**).

## Bearings with contact seals

Bearings with contact seals, referred to simply as seals, are preferred for arrangements where contamination is moderate and the presence of water or moisture cannot be ruled out, or where maximum bearing service life and minimum maintenance are required.

SKF has developed a variety of seal designs (→ **fig. 49**). Depending on the bearing type or size, the seal makes contact with:

- the inner ring or inner ring shoulder (**a**)
- the recess in the inner ring shoulder (**b, c**)
- the lead-in chamfer on the sides of the inner ring raceway (**d, e**)
- the outer ring (**f**)

Fig. 48

Fig. 49

F

## Design considerations

For deep groove ball bearings, SKF has developed additional seal types (→ **fig. 50**):

- The SKF non-contact seal (**a**) forms an extremely narrow gap with the land of the inner ring shoulder.
- The SKF low-friction seal (**b, c**) makes almost no contact with the inner ring, but provides very good low-friction operation.
- The SKF WAVE seal (**d**), a spring-loaded radial shaft seal designed for oil lubricated applications, is incorporated on one side of the bearing (→ *ICOS oil sealed bearing units*, **page 304**)

SKF bearing seals are generally made of an elastomeric compound that is vulcanized to a sheet steel reinforcement ring. Depending on the series, size and the application requirements, typical seal materials are:

- acrylonitrile-butadiene rubber (NBR)
- hydrogenated acrylonitrile-butadiene rubber (HNBR)
- fluoro rubber (FKM)
- polyurethane (PUR)

The selection of the appropriate seal material depends on the expected operating temperature and the lubricant that is applied. For permissible operating temperatures, refer to *Seal materials* (→ **page 155**).

## External seals

For bearing arrangements where the effectiveness of the seal under specific operating conditions is more important than space considerations or cost, there are several possible seal types to choose from.

For seals that are not supplied by SKF, the information provided in the following section is to be used as a guideline only. SKF does not accept liability for the performance of any products not supplied by SKF. Make sure to understand the seal's performance criteria before incorporating that seal into an application.

## Non-contact seals

The simplest seal used outside a bearing is the gap-type seal, which creates a small gap between the shaft and housing (→ **fig. 51**). This type of seal is adequate for grease lubricated applications that operate in dry, dust-free environments. To enhance the effectiveness of this seal, one or more concentric grooves can be machined in the housing bore at the shaft end (→ **fig. 52**). The grease emerging through the gap fills the grooves and helps to prevent the entry of contaminants.

With oil lubrication and horizontal shafts, helical grooves – right-hand or left-hand depending on the direction of shaft rotation – can be machined into the shaft or housing bore (→ **fig. 53**). These grooves are designed to return emerging oil to the bearing position. Therefore, it is essential that the shaft rotates in one direction only.

Fig. 51

Fig. 52

Fig. 53

F

## Design considerations

Single or multi-stage labyrinth seals, typically used with grease lubrication, are considerably more effective than simple gap-type seals, but are also more expensive. Their effectiveness can be further improved by periodically applying a water-insoluble grease, such as a grease with a lithium-calcium thickener, via a duct to the labyrinth passages. The passages of the labyrinth seal can be arranged axially (→ **fig. 54**) or radially (→ **fig. 55**), depending on the housing type (split or non-split), mounting procedures, available space etc. The width of the axial passages of the labyrinth (→ **fig. 54**) remain unchanged when axial displacement of the shaft occurs in operation and can therefore be very narrow. If angular misalignment of the shaft relative to the housing can occur, labyrinths with inclined passages can be used (→ **fig. 56**).

Effective and inexpensive labyrinth seals can be made using commercially available products, such as SKF sealing washers (→ **fig. 57**). Sealing effectiveness increases with the number of washer sets and can be further improved by incorporating flocked washers. For additional information on these sealing washers, refer to *Power transmission seals* (→ [skf.com/seals](http://skf.com/seals)).

Rotating discs (→ **fig. 58**) are often fitted to the shaft to improve the sealing action of shields. Flingers, grooves or discs are used for the same purpose with oil lubrication. The oil from the flinger is collected in a channel in the housing and returned to the housing sump through suitable ducts (→ **fig. 59**).

## Design considerations

### Contact seals

There are four common types of contact seals:

- radial shaft seals (→ **figs. 60 and 61**)
- V-ring seals (→ **fig. 62**)
- axial clamp seals (→ **fig. 63**)
- mechanical seals (→ **fig. 64, page 236**)

The seal type selected for a particular application typically depends on its primary purpose (retain lubricant or exclude contaminants), type of lubricant (oil, grease or other) and operating conditions (speed, temperature, level of contamination).

### Radial shaft seals

Radial shaft seals (→ **figs. 60 and 61**) are contact seals that are used mainly in oil lubricated applications. These ready-to-mount components typically consist of a metal reinforcement or casing, a synthetic rubber body, a seal lip and a garter spring. The seal lip is pressed against the shaft by the garter spring. Depending on the seal material and medium to be retained and/or excluded, radial shaft seals can be used at temperatures between  $-60$  and  $+190$  °C ( $-75$  to  $375$  °F).

The seal counterface, that part of the shaft where the seal lip makes contact, is of vital importance to sealing effectiveness. The surface hardness of the counterface should be at least 55 HRC at a depth of at least 0,3 mm. The surface roughness should be in accordance with ISO 4288 and within the guidelines of  $R_a = 0,2$  to  $0,8$   $\mu\text{m}$ . In applications where speeds are slow, lubrication is good, and contamination levels are minimal, a lower hardness can be acceptable. To avoid the pumping effect induced by helical grinding marks, SKF recommends plunge grinding the counterface.

If the primary purpose of the radial shaft seal is lubricant retention, the seal should be mounted with the lip facing inward (→ **fig. 60**). If the primary purpose is to exclude contaminants, the lip should face outward, away from the bearing (→ **fig. 61**).

Fig. 60

Fig. 61

### V-ring seals

V-ring seals (→ **fig. 62**) can be used with either oil or grease lubrication. The elastic rubber body of the seal grips the shaft and rotates with it, while the seal lip exerts a light axial pressure on a stationary component, such as a housing. Depending on the material, V-rings can be used at operating temperatures between  $-40$  and  $+150$  °C ( $-40$  to  $300$  °F). They are simple to install and permit relatively large angular misalignments of the shaft at slow speeds.

A surface roughness of  $R_a = 2$  to  $3$   $\mu\text{m}$  is sufficient for the counterface. At circumferential speeds above  $8$  m/s, the body of the seal must be located axially on the shaft. At speeds above  $12$  m/s, the body must be prevented from lifting from the shaft. A sheet metal support ring can be used to do this. When circumferential speeds exceed  $15$  m/s, the seal lip lifts away from the counterface and the V-ring becomes a gap-type seal.

The good sealing ability of a V-ring seal can be attributed to the body of the seal, which acts as a flinger, repelling dirt and fluids. As a result, these seals are generally arranged outside the housing in grease lubricated applications and inside the housing, with the lip pointing away from the bearing, in oil lubricated applications. Used as a secondary seal, V-rings protect the primary seal from excessive contaminants and moisture.

### Axial clamp seals

Axial clamp seals (→ **fig. 63**) are used as secondary seals for large diameter shafts in applications where protection is required for the primary seal. They are clamped in position on a non-rotating component and seal axially against a rotating counterface. For this type of seal, it is sufficient if the counterface is fine turned and has a surface roughness  $R_a = 2,5$   $\mu\text{m}$ .

Fig. 62

Fig. 63

## Design considerations

### Mechanical seals

Mechanical seals (→ **fig. 64**) are used to seal grease or oil lubricated applications where speeds are relatively slow and operating conditions difficult and arduous. They consist of two sliding steel rings with finely finished sealing surfaces and two plastic cup springs (Belleville washers), which position the sliding rings in the housing bore and provide the necessary preload force to the sealing surfaces. There are no special demands on the mating surfaces in the housing bore.

### Other seals

Felt seals (→ **fig. 65**) are generally used with grease lubrication. They are simple, cost-effective and can be used at circumferential speeds of up to 4 m/s and at operating temperatures up to 100 °C (205 °F). The counterface should be ground to a surface roughness  $R_a \leq 3,2 \mu\text{m}$ . The effectiveness of a felt seal can be improved substantially by mounting a simple labyrinth seal as a secondary seal. Before being inserted in the housing groove, felt seals should be soaked in oil at about 80 °C (175 °F) prior to mounting.

Metal seals (→ **fig. 66**) are simple, cost-effective and space-saving seals for grease lubricated bearings, particularly deep groove ball bearings. The seals are clamped against either the inner or outer ring and exert a resilient axial pressure against the other ring. After a certain running-in period, these seals become non-contact seals by forming a very narrow gap with the rotating ring.

For additional information about seals supplied by SKF, refer to *Power transmission seals* (→ [skf.com/seals](http://skf.com/seals)).

# Basics of lubrication

Rolling bearings need to be adequately lubricated to operate reliably and to prevent direct metal-to-metal contact between the rolling elements, raceways, cages and other components. The lubricant also inhibits wear and protects the bearing surfaces against corrosion. The choice of a suitable lubricant and lubrication method is important, as is proper maintenance.

A wide assortment of greases, oils and alternative lubricants like graphite-based compounds are available to lubricate rolling bearings. Selecting a lubricant depends primarily on the operating conditions such as the temperature range and speeds. However, other factors like vibration and loads can also influence lubricant selection.

Generally, the most favourable operating temperatures can be obtained when the minimum amount of lubricant needed to reliably lubricate a bearing is provided. However, when the lubricant has additional functions, such as sealing or removing heat, additional amounts of lubricant may be required.

The lubricant in a bearing arrangement gradually loses its lubricating properties as a result of mechanical working, ageing and the build-up of contaminants. It is therefore necessary for grease to be replenished or renewed and for oil to be filtered and changed at regular intervals.

The information and recommendations in this section relate to bearings without integral seals or shields. SKF bearings and bearing units with an integral seal and/or shield on both sides are factory-greased. Information about the standard greases used by SKF is provided in the relevant product chapters, together with a brief description of the performance data.

Under normal operating conditions, the service life of the grease in sealed bearings exceeds the service life of the bearing so that, with some exceptions, no provision is made for the relubrication of these bearings.

For purposes of this discussion, normal operating conditions can be defined as:

- constant loads in magnitude and direction
- loads equal to or larger than the recommended minimum load and at least:
  - 0,01 C for ball bearings
  - 0,02 C for roller bearings
- constant speed, but not higher than the permissible speed
- appropriate operating clearance
- for grease lubrication:
  - only steady state conditions (after several hours of operation)
  - lithium soap grease with mineral oil
  - bearing free volume filled approximately 30%
  - minimum ambient temperature 20 °C (70 °F)
- for oil lubrication:
  - oil bath, oil-air or oil jet
  - viscosity range from 2 to 500 mm<sup>2</sup>/s

### Ring centred cages

Bearings with ring centred cages are primarily designed for oil lubrication. Grease lubrication can be used for moderate speeds. Information about the cage designs and the limits are provided in the relevant product chapters, if applicable.

### Lubricant specifications

Differences in the lubricating properties of seemingly identical lubricants – particularly grease – produced at different locations, or even different production batches from the same location, can exist. Therefore, SKF cannot accept liability for any lubricant or its performance. The user is therefore advised to specify lubricant properties in detail to obtain the most suitable lubricant for the application.

### Viscosity ratio $\kappa$

The importance of the oil viscosity to form a hydrodynamic oil film that separates the bearing contact surfaces is already mentioned under *Lubrication conditions – the viscosity ratio  $\kappa$*  (→ **page 71**). That information applies equally to the base oil viscosity of lubricating greases and oils.

The condition of the lubricant is described by the viscosity ratio  $\kappa$  as the ratio of the actual viscosity  $\nu$  to the rated viscosity  $\nu_1$  for adequate lubrication, when the lubricant is at normal operating temperature.

$$\kappa = \frac{\nu}{\nu_1}$$

where

$\kappa$  = viscosity ratio

$\nu$  = actual operating viscosity of the lubricant  
[mm<sup>2</sup>/s]

$\nu_1$  = rated viscosity of the lubricant depending on the bearing mean diameter and rotational speed [mm<sup>2</sup>/s]

To separate the bearing contact surfaces, a minimum viscosity ratio  $\kappa = 1$  is required. Full-film conditions exist when  $\kappa \geq 4$ , i.e. a sufficient hydrodynamic film is formed for adequate lubrication. However, SKF recommends limiting  $\kappa$  to 4, otherwise the frictional heat decreases the operating viscosity.

In applications where  $\kappa < 1$ , a sufficient hydrodynamic film cannot be formed and metal-to-metal contact may occur. The use of lubricants containing extreme pressure or anti-wear additives (→ *Load carrying ability*, **page 248**) might extend bearing service life.

For oil lubricated applications where  $\kappa < 0,4$ , an oil with EP additives must be used.

In applications where  $\kappa < 1$ , hybrid bearings (→ *Hybrid bearings*, **page 1219**) can be considered. Even under inadequate lubrication conditions, there is reduced risk of smearing between silicon nitride and steel surfaces.

## Grease lubrication

The majority of rolling bearings are grease lubricated. Compared to oil, the advantage is that grease is more easily retained in the bearing arrangement, particularly where shafts are inclined or vertical. Grease also contributes to sealing the arrangement against solid and liquid contaminants as well as moisture.

The terms used to categorize speed ranges, temperatures and loads for grease lubrication can differ from those used for bearings. Terms typically used for grease lubricated bearings are defined in the following tables:

- **table 1:** speed ranges for grease lubricated radial bearings
- **table 2:** grease temperature
- **table 3:** load ranges for greases

The quantity of grease applied to a bearing depends on the application. Too little grease leads to metal-to-metal contact and premature bearing failure. Excessive amounts of grease cause the operating temperature within the bearing to rise rapidly, particularly when running at high speeds. Bearings with seals or shields (capped bearings) are filled by SKF with a sufficient amount of grease to provide long bearing service life.

Depending on the speed range (→ **table 1**), SKF recommends the following grease fill percentages for bearings:

- 100% for slow speeds
- 30–50% for medium to high speeds

The free volume in the housing should be partly filled with grease. Before operating at full speed, the excess grease in the bearing must be given time to settle or escape during a running-in period. At the end of the running-in period, the operating temperature drops considerably, indicating that the grease has been distributed in the bearing arrangement.

In applications where bearings operate at very slow speeds and good protection against contaminants and corrosion is required, SKF recommends filling the housing up to 90% with grease.

## Lubricating greases

Lubricating greases consist of a mineral or synthetic oil combined with a thickener. The thickeners are usually metallic soaps. However, other thickeners like polyurea are also available, and can be used in applications where there are, for example, high temperatures. Additives are also included to enhance certain properties of the grease. The consistency of the grease depends largely on the type and concentration of the thickener, and on the operating temperature of the application. When selecting a grease, the most important factors to be considered are:

- temperature range
- consistency
- base oil viscosity
- protection against corrosion
- load carrying ability
- miscibility

### Temperature range – the SKF traffic light concept

The temperature range over which a grease can be used depends largely on the type of base oil and thickener as well as the additives. The relevant temperatures are schematically illustrated in **diagram 1** in the form of a “double traffic light”.

The extreme temperature limits, low and high, are well-defined.

- The low temperature limit (LTL), the lowest temperature at which a grease enables the bearing to be started up without difficulty, is largely determined by the base oil and its viscosity.
- The high temperature limit (HTL) is determined by the type of thickener and its dropping point. The dropping point is the temperature at which a grease loses its consistency and becomes a fluid.

As indicated in **diagram 1** by the red zones, SKF does not recommend using a grease above or below its temperature limits to lubricate bearings. Although grease suppliers indicate the specific values for the low and high temperature limits in their product literature, the temperatures for reliable operation are indicated by the SKF values for the following limits:

- low temperature performance limit (LTPL)
- high temperature performance limit (HTPL)

Within these two limits, which is indicated by the green zone in **diagram 1**, the grease fulfils its function reliably and the relubrication interval or grease life can be determined accurately. Since the definition of the high temperature performance limit is not standardized internationally, care must be taken when interpreting supplier data.

At temperatures above the high temperature performance limit (HTPL), grease degrades with increasing rapidity and the by-products of oxidation have a detrimental effect on the lubricant. Therefore, temperatures in the amber zone, between the high temperature performance limit (HTPL) and the high temperature limit (HTL), should only be allowed to occur for very short periods and not longer than a few hours.

Diagram 1

## The SKF traffic light concept

An amber zone also exists for low temperatures. With decreasing temperature, the consistency (stiffness) of grease increases and the tendency of grease to bleed decreases. This ultimately leads to an insufficient supply of lubricant reaching the contact surfaces of the rolling elements and raceways. In **diagram 1**, this temperature limit is indicated by the low temperature performance limit (LTPL). Values for the low temperature performance limit are different for roller bearings than for ball bearings. Since ball bearings are easier to lubricate than roller bearings, the low temperature performance limit is less important for ball bearings. For roller bearings, however, serious damage can result when the bearings are operated continuously below this limit. Short periods in this zone, such as during a cold start, are not harmful because the heat caused by frictional heat brings the bearing temperature into the green zone.

### Temperature zones

Temperature zones differ from grease to grease and can only be determined by functional bearing testing.

Typical temperature zones for commonly available NLGI 2 greases without EP additives, which are normally used for rolling bearings, are shown in **diagram 2**. Since the data for each grease type is a summary of many greases of more or less similar composition, the transitions for each zone are not distinct, but fall within a certain range.

Temperature zones for SKF greases are shown in **diagram 3**. These temperature zones are based on extensive tests conducted in SKF laboratories.

The temperatures shown in **diagrams 2** and **3** relate to the measured temperature of the non-rotating ring in operation.

### Consistency

Greases are divided into various consistency classes in accordance with the National Lubricating Grease Institute (NLGI). The consistency of lubricating grease should not change drastically when operated within its specified temperature range. Greases that soften at elevated temperatures may leak from the bearing arrangement. Those that stiffen at low temperatures may restrict bearing rotation or limit oil bleeding.

Greases with a metallic soap thickener and a consistency of 1, 2 or 3 on the NLGI scale are typically used for rolling bearings. The most common greases have a consistency of 2. Lower consistency greases are preferred for low temperature applications or to improve pumpability. Greases with a consistency of 3 are recommended for bearing arrangements with a vertical shaft where a baffle plate is arranged beneath the bearing to retain the grease in the bearing.

In applications subjected to vibration, the grease is heavily worked as it is continuously thrown back into the bearing by vibration. For these applications, higher consistency greases that do not change their consistency during operation may help.

Greases thickened with polyurea can soften or harden depending on the shear rate in the application. Therefore, in applications with vertical shafts, there is a danger that under

certain conditions, polyurea grease leaks, irrespective of the operating temperature.

### Base oil viscosity

The base oil viscosity for greases typically used to lubricate rolling bearings lies between 15 and 500 mm<sup>2</sup>/s at 40 °C (105 °F). Greases based on oils having higher viscosities than 500 mm<sup>2</sup>/s at 40 °C (105 °F) bleed oil so slowly that the bearing may not be adequately lubricated. Therefore, if a viscosity higher than 500 mm<sup>2</sup>/s at 40 °C (105 °F) is required because of slow speeds, and for bearings operating at extremely high or low temperatures, extreme care must be taken. Under these conditions, contact the SKF application engineering service.

Base oil viscosity also governs the maximum recommended speed for a bearing. The permissible speed for grease is also influenced by the shear strength of the grease which is determined by the thickener. To indicate the speed capability, grease manufacturers often quote a speed factor, which can be calculated using

$$A = n d_m$$

where

A = speed factor [mm/min]

d<sub>m</sub> = bearing mean diameter [mm]  
= 0,5 (d + D)

n = rotational speed [r/min]

If the speed factor A exceeds 70% of the recommended limits (→ **table 5, page 257**), verify the influence of the selected lubricant on the speed limits that are provided under **Speeds** (→ **page 117**) and check whether the rotational speed is within these limits.

For extreme high-speed applications, contact the SKF application engineering service.

Diagram 2

The SKF traffic light concept – standard greases

Diagram 3

The SKF traffic light concept – SKF greases

For operating temperatures > 150 °C (300 °F), SKF recommends SKF LGET 2 grease.

### Protection against corrosion

Grease should also protect the bearing against corrosion and should not be washed out of the bearing arrangement if water is present. The type of thickener solely determines the ability of the grease to resist water washout. Thickeners with very good washout resistance include lithium complex, calcium complex, and polyurea greases. The ability of a grease to inhibit corrosion is determined by the properties of the rust inhibitor additive for that grease.

For very slow-speed applications, filling the housing up to 90% with grease can improve corrosion protection and help prevent the ingress of water.

### Load carrying ability

If the thickness of the hydrodynamic lubricant film is not sufficient to prevent metal-to-metal contact, bearing service life can be extended significantly by using a lubricant containing extreme pressure (EP) or anti-wear (AW) additives.

In applications where  $\kappa > 1$  ( $\rightarrow$  *Viscosity ratio*  $\kappa$ , page 241), SKF does not generally recommend using EP or AW additives. However, there are circumstances where EP/AW additives may be beneficial such as if excessive sliding between the rollers and raceways is expected.

### Extreme pressure additives

EP (extreme pressure) additives are an option to overcome metal-to-metal contact of the asperities on the contact surfaces. Elevated temperatures, induced by local asperity contact, activate these additives, which promote mild chemical wear at the points of contact. The result is a smoother surface, lower contact stresses and extended bearing service life.

Some modern EP additives contain sulphur-phosphorus, which may become chemically active even without asperity contact. In these cases, high operating temperatures and/or contact stresses become the catalyst. The resulting chemical activity may not be restricted to the asperity contacts and can have a detrimental effect on the strength of the bearing steel matrix. This can promote corrosion/diffusion mechanisms in the contacts and may lead to accelerated bearing damage, usually initiated by micro spalls.

Therefore, SKF recommends using EP additives that are less reactive in applications with operating temperatures  $> 80\text{ }^{\circ}\text{C}$  ( $175\text{ }^{\circ}\text{F}$ ) and  $< 100\text{ }^{\circ}\text{C}$  ( $210\text{ }^{\circ}\text{F}$ ). For very slow speeds, solid lubricant additives such as graphite and molybdenum disulfide ( $\text{MoS}_2$ ) can be used to enhance the EP effect. These additives should have a high purity level and a very small particle size. Otherwise, dents due to overrolling of the particles might reduce bearing service life.

For additional information about EP additives, contact the SKF application engineering service.

### Anti-wear additives

AW (anti-wear) additives, like EP additives, prevent direct metal-to-metal contact. However, the way they work is very different. The main difference is that AW additives build a protective layer that adheres to the surface of the metal. The asperities can then slide over each other, avoiding direct contact. The surface finish is therefore not affected by mild wear as is the case with EP additives. Note that AW additives, like EP additives, may contain elements that can weaken the steel structure close to the surface.

Certain thickeners (e.g. calcium sulphonate complex) also provide an EP/AW effect without chemical activity and the resulting effect on bearing fatigue life. These thickeners do not have a temperature limit.

For additional information about AW additives, contact the SKF application engineering service.

### Miscibility

If it becomes necessary to change from one grease to another, the miscibility or the ability to mix greases without adverse effects should be considered. If incompatible greases are mixed, the resulting consistency can change so dramatically that bearing damage due to severe leakage could result.

Greases with the same thickener and similar base oils can generally be mixed without any detrimental consequences. For example, a lithium thickener / mineral oil grease can generally be mixed with another lithium thickener / mineral oil grease. Also, some greases with different thickeners, such as

calcium complex and lithium complex, are miscible.

In cases where changing from one grease to another could cause low grease consistency and grease escaping from the bearing arrangement, all the old grease should be removed from the arrangement and the lubrication ducts (→ *Relubrication*, **page 252**).

The preservative with which SKF bearings are treated is compatible with the majority of lubricating greases with the possible exception of polyurea greases. Note that synthetic fluorinated oil based greases using a PTFE thickener, e.g. SKF LGET 2 grease, are not compatible with standard preservatives and the preservatives must be removed before applying grease.

For additional information, contact the SKF application engineering service.

#### WARNING

PTFE exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions under *Seal materials* (→ **page 155**).

## SKF greases

The assortment of SKF greases for rolling bearings covers virtually all application requirements. These greases have been developed based on the latest information about rolling bearing lubrication. SKF continuously monitors the quality of its greases prior to use or sale.

The most important technical specifications for SKF greases, together with a quick selection guide, are provided in **table 4** (→ **page 250**). The temperature ranges where the SKF greases can be used are schematically illustrated according to the SKF traffic light concept in **diagram 3** (→ **page 247**).

## Relubrication

Rolling bearings have to be relubricated if the service life of the grease is shorter than the expected service life of the bearing. Relubrication should always occur while the existing lubricant is still satisfactory.

The time at which the bearing should be relubricated depends on many related factors. These include:

- bearing type and size
- speed
- operating temperature
- grease type
- space around the bearing
- bearing environment

It is only possible to base recommendations on statistical rules. The SKF relubrication intervals are defined as the time period, at the end of which 99% of the bearings are still reliably lubricated. This represents the  $L_{10}$  grease life.

SKF recommends using experience based data from actual applications and tests, together with the estimated relubrication intervals provided.

For many applications, there is a temperature limit for standard greases when the bearing ring with the highest temperature exceeds an operating temperature of 100 °C (210 °F). Above this temperature, special greases should be used. In addition, the temperature limits of the bearing and adjacent machine components, such as external seals, should be taken into consideration.

For additional information about high temperature applications, contact the SKF application engineering service.

### Relubrication intervals

The relubrication intervals  $t_f$  for bearings with a rotating inner ring on horizontal shafts under normal and clean operating conditions can be obtained from **diagram 4** (→ **page 256**) as a function of:

- the speed factor A multiplied by the relevant bearing factor  $b_f$

where

$A = n d_m$  [mm/min]

$b_f$  = bearing factor dependent on bearing type and load conditions (→ **table 5, page 257**)

$d_m$  = bearing mean diameter [mm]  
= 0,5 (d + D)

$n$  = rotational speed [r/min]

- the load ratio C/P

The relubrication interval  $t_f$  is the estimated number of operating hours that a high-quality grease, consisting of mineral oil and a lithium base thickener, can perform adequately when the operating temperature is 70 °C (160 °F).

When bearing operating conditions differ, the relubrication intervals (→ **diagram 4, page 256**) need to be adjusted (→ *Adjustments of relubrication intervals due to operating conditions and bearing types*).

If the speed factor A exceeds 70% of the recommended limits (→ **table 5, page 257**), verify the influence of the selected lubricant on the speed limits that are provided under *Speeds* (→ **page 117**) and check whether the rotational speed is within these limits.

When using high performance greases, an extended relubrication interval and grease life may be possible.

For grease life of capped bearings, refer to the relevant product chapters.

For additional information, contact the SKF application engineering service.

### Adjustments of relubrication intervals due to operating conditions and bearing types

#### Operating temperature

To account for the accelerated ageing of grease with increasing temperature, SKF recommends halving the obtained intervals (→ **diagram 4, page 256**) for every 15 °C (27 °F) increase in operating temperature above 70 °C (160 °F). The high temperature performance limit HTPL for the grease (→ **diagram 1, page 245**) should not be exceeded.

The relubrication interval  $t_f$  may be extended at temperatures below 70 °C (160 °F) if the temperature is not close to the lower temperature performance limit LTPL (→ **diagram 1, page 245**). SKF does not recommend extending the relubrication interval  $t_f$  by more than a factor of two.

Do not extend the obtained  $t_f$  values (→ **diagram 4, page 256**) for full complement bearings or thrust roller bearings. Moreover, it is not advisable to use relubrication intervals in excess of 30 000 hours.

### Vertical shafts

For bearings on vertical shafts, the intervals obtained from **diagram 4** (→ **page 256**) should be halved.

The use of an effective seal, shield or baffle plate is a prerequisite to prevent grease leaking from the bearing arrangement.

### Vibration

Moderate vibration does not have a negative effect on grease life. However, high vibration and shock levels, such as those in vibrating screen applications, cause the grease to churn. In these cases, the relubrication interval should be reduced. If, during operation, the grease becomes too soft, use a more mechanically stable grease, e.g. SKF LGHB 2 or grease with higher stiffness up to NLGI 3.

### Outer ring rotation

In applications where the outer ring rotates, the speed factor A is calculated differently. In this case, use the bearing outside diameter D instead of  $d_m$ . The use of an effective seal is a prerequisite to avoid grease leakage.

In applications where there are high outer ring speeds (i.e. > 40% of the reference speed listed in the product tables), greases with good oil bleeding properties should be applied.

For spherical roller thrust bearings with a rotating housing washer, oil lubrication is recommended.

### Contamination

In applications where the ingress of solid contaminants is an issue, more frequent relubrication than indicated by the relubrication interval is necessary. Relubrication reduces the level of contamination while reducing the damaging effects caused by overrolling the

particles. Liquid contaminants such as water and/or process fluids also require a reduced relubrication interval. In case of severe contamination, continuous relubrication should be considered.

## Lubrication

### Very slow speeds

Selecting the proper grease and grease fill is very important for slow speed applications. Bearings that operate at very slow speeds under light loads require a low consistency grease. Bearings that operate at slow speeds under heavy loads should be lubricated with a grease that has a high viscosity base oil containing EP additives.

Solid additives such as graphite and molybdenum disulfide ( $\text{MoS}_2$ ) can be considered for a speed factor  $A < 20\,000$  mm/min.

### High speeds

Relubrication intervals for bearings used at speeds above the recommended speed factor  $A$  (→ **table 5, page 257**) should only be applied when using special greases or modified bearing executions such as hybrid bearings. In these cases, continuous relubrication techniques such as circulating oil or the oil-air method are more effective than grease.

### Heavy and very heavy bearing loads

For bearings operating at a speed factor  $A > 20\,000$  mm/min and subjected to a load ratio  $C/P < 4$ , the relubrication interval is reduced to the point that SKF recommends continuous grease relubrication or the oil bath lubrication method.

In applications where the speed factor  $A < 20\,000$  mm/min and the load ratio  $C/P = 1-2$ , refer to *Very slow speeds*.

For heavy loads and high speeds, SKF generally recommends a circulating oil system with auxiliary cooling.

### Very light bearing loads

In many cases, the relubrication interval can be extended if the loads are light, i.e.  $C/P = 30$  to 50. To obtain satisfactory operation, the bearings should be subjected to the minimum load as stated in the relevant product chapters.

### Misalignment

Static misalignment, within the permissible limits, does not adversely affect grease life in spherical roller bearings, self-aligning ball bearings or CARB toroidal roller bearings.

### Large bearings

Large roller bearings,  $d > 300$  mm, used in process machinery, require a proactive approach. For these critical applications, SKF recommends strict adherence to the relubrication quantities but with shorter initial relubrication intervals.

Prior to relubrication, check the used grease for both solid and liquid contaminants. Also, check the sealing system completely, looking for wear, damage and leaks. If, over time, the condition of the grease and associated components is found to be satisfactory, the relubrication interval can be increased gradually.

SKF recommends a similar procedure for spherical roller thrust bearings, prototype machines and upgrades of high-density power equipment or wherever application experience is limited.

### Cylindrical roller bearings

The relubrication intervals (→ **diagram 4, page 256**) are valid for cylindrical roller bearings fitted with:

- a glass fibre reinforced PA66 cage, roller centred, designation suffix P
- a machined brass cage, roller centred, designation suffix M

The obtained relubrication intervals (→ **diagram 4, page 256**) should be halved and a grease with good oil bleeding properties should be applied to cylindrical roller bearings with:

- a stamped steel cage, roller centred, no designation suffix or suffix J
- a machined brass cage, inner or outer ring centred, designation suffixes MA, MB, MH, ML or MP
- a sheet steel cage, inner or outer ring centred, designation suffixes JA or JB

**Observations**

If, during testing, the determined value for the relubrication interval  $t_r$  is too short for a particular application, SKF recommends the following:

- Check the bearing operating temperature.
- Check whether the grease contains solid or liquid contaminants.
- Check the operating conditions, e.g. load or misalignment.
- Check whether a more suitable grease is necessary.

Relubrication intervals at operating temperatures of 70 °C (160 °F)

## Relubrication procedures

The relubrication procedure generally depends on the application and on the relubrication interval  $t_r$ . SKF recommends one of the following procedures:

- Replenishment is a convenient and preferred procedure if the relubrication interval is shorter than six months. It enables uninterrupted operation and provides, when compared with continuous relubrication, a lower steady state temperature.
- Renewing the grease fill is generally recommended when the relubrication interval is longer than six months. This procedure is often applied as part of a bearing maintenance schedule.
- Continuous relubrication is used when the estimated relubrication intervals are short due to the adverse effects of contamination, or when other relubrication methods are inconvenient because access to the bearing is difficult. SKF does not recommend continuous relubrication for applications with high rotational speeds since the intensive churning of the grease can lead to very high operating temperatures and destruction of the grease thickener structure.

When using different bearings in a bearing arrangement, it is common practice to apply the lowest estimated relubrication interval for all bearings in the arrangement. The guidelines and grease quantities for the three alternative procedures are provided below.

### Replenishment

As mentioned in the introduction of *Lubrication*, the free volume in the bearing should be completely filled during installation, while the free volume in the housing generally should be partly filled. Depending on the intended method of replenishment, SKF recommends the following grease fill percentages for this free volume in the housing:

- 40% when replenishing from the side of the bearing (→ **fig. 1**).
- 20% when replenishing through the lubrication holes in the bearing inner or outer ring (→ **fig. 2**).

Suitable quantities for replenishment from the side of a bearing can be obtained from

$$G_p = 0,005 D B$$

and for replenishment through the bearing outer or inner ring from

$$G_p = 0,002 D B$$

where

$G_p$  = grease quantity to be added when replenishing [g]

$B$  = total bearing width [mm]  
(for tapered roller bearings use  $T$ ,  
for thrust bearings use height  $H$ )

$D$  = bearing outside diameter [mm]

Fig. 1

Fig. 2

To apply grease with a grease gun, a grease fitting is needed on the housing. If contact seals are used, an escape hole in the housing should also be provided so that excess grease does not build up in the space surrounding the bearing (→ **figs. 1 and 2**). Otherwise, this can cause a permanent increase in bearing temperature. The escape hole should be plugged when high-pressure water is used for cleaning.

Excess grease collecting in the space surrounding the bearing can cause temperature peaks, which can have a detrimental effect on the grease as well as the bearing. It is more pronounced when bearings operate at high speeds. In these cases, SKF recommends using a grease flinger in combination with an escape hole. This prevents over-lubrication and enables relubrication to be performed while the machine is in operation. A grease flinger is basically a disc that rotates with the shaft and forms a narrow gap together with the housing end cover (→ **fig. 3**). Excess and used grease is flung into an annular cavity and leaves the housing through an opening on the underside of the end cover.

For additional information about the design and dimensioning of grease flingers, contact the SKF application engineering service.

To be sure that fresh grease actually reaches the bearing and replaces the old grease, the lubrication duct in the housing should either feed the grease adjacent to the outer ring side face (→ **figs. 1 and 4**) or, preferably, into the bearing. To facilitate efficient lubrication, some bearing types, e.g. spherical roller bearings, are provided with an annular groove and/or one or more lubrication holes in the inner or outer ring (→ **figs. 2 and 5**).

Fig. 3

Fig. 4

Fig. 5

G

To effectively replace used grease, it is important to relubricate the bearing while the machine is in operation. In cases where the machine is not in operation, the bearing should be rotated during replenishment. When lubricating the bearing directly through the inner or outer ring, the fresh grease is applied directly to the free volume in the bearing. Therefore, the amount of grease needed is reduced, when compared with relubricating from the side. It is assumed that the lubrication ducts were filled with grease during the mounting process. If not, a larger quantity of grease is needed to compensate for the empty ducts during the first replenishment.

Where long lubrication ducts are used, check whether the grease can be adequately pumped at the prevailing ambient temperature.

The grease in the housing should be replaced when the free volume in the housing is approximately 75% full. When relubricating from the side and starting with 40% initial fill of the housing, the complete grease fill should be replaced after approximately five replenishments. Due to the lower initial fill of the housing and the reduced topping-up quantity during replenishment when relubricating the bearing directly through the inner or outer ring, renewal is only required in exceptional cases.

### Renewing the grease fill

When renewing the grease fill at the estimated relubrication interval or after a certain number of replenishments, the used grease in the bearing and housing should be completely removed and replaced. The used grease should be disposed of in an environmentally safe and responsible way.

Filling the bearing and housing with grease should be done in accordance with the guidelines provided under *Replenishment* (→ page 258).

To renew the grease fill, the housing should be accessible and easily opened. The cap of split housings and the covers of non-split housings can usually be removed to expose the bearing. After removing the used grease, fresh grease should first be packed between the rolling elements. Precautions should be taken to prevent contaminants from being introduced into the bearing, housing or grease container. SKF recommends using grease resistant gloves to prevent any allergic skin reactions.

When housings are less accessible, but are provided with grease fittings and escape holes, it is possible to completely renew the grease fill by relubricating several times in close succession until fresh grease is purged from the housing. This procedure requires much more grease than is needed for manual renewal. In addition, this method of renewal has speed limitations. At high speeds, temperatures can increase as a result of grease churning.

## Continuous relubrication

This procedure is used when the calculated relubrication interval is very short, e.g. due to the adverse effects of contamination, or when other procedures of relubrication are inconvenient, e.g. access to the bearing is difficult. Due to the excessive churning of the grease, which can lead to increased temperature, continuous lubrication is only recommended when rotational speeds are relatively slow such as the following speed factors:

- $A < 150\,000$  mm/min for ball bearings
- $A < 75\,000$  mm/min for roller bearings

In these cases, the initial grease fill for the housing can be up to 90% and the quantity for relubrication per time unit is derived from the equations for  $G_p$  (→ *Replenishment*, **page 258**) by spreading the required quantity over the relubrication interval.

When using continuous relubrication, check whether the grease can be adequately pumped through the ducts at the prevailing ambient temperature.

Continuous lubrication can be achieved via single-point or multi-point automatic lubricators, e.g. SYSTEM 24 or SYSTEM MultiPoint.

For additional information, contact the SKF application engineering service.

Centralized lubrication systems, such as SYSTEM MonoFlex, SYSTEM ProFlex, SYSTEM DuoFlex and SYSTEM MultiFlex, can reliably deliver grease in a wide range of quantities. For additional information about SKF lubrication systems, visit [skf.com/lubrication](https://skf.com/lubrication).

# Oil lubrication

Oil is generally used to lubricate rolling bearings when:

- high speeds or operating temperatures preclude the use of grease
- excessive heat has to be removed from the bearing position
- adjacent components (gears etc.) are lubricated with oil

To extend bearing service life, all methods of bearing lubrication that use clean oil are acceptable. These include:

- the circulating oil lubrication method
- the oil jet method
- the oil-air method

When using the circulating oil or oil-air method, adequately dimensioned ducts should be provided so that oil flowing from the bearing can leave the arrangement.

## Oil lubrication methods

### Oil bath

The simplest method of oil lubrication is the oil bath (→ **fig. 6**). The oil, which is picked up by the rotating components of the bearing, is distributed within the bearing and then flows back to the sump in the housing. The oil level should almost reach the centre of the lowest rolling element when the bearing is stationary. SKF recommends the use of oil levellers such as the SKF LAHD 500 to maintain the correct oil level.

When operating at high speed, the oil level can drop significantly and the housing can become overfilled by the oil leveller. If this occurs, contact the SKF application engineering service.

Fig. 6

### Oil pick-up ring

For bearing applications where speeds and operating temperatures require oil to be delivered reliably, SKF recommends using an oil pick-up ring (→ **fig. 7**). The pick-up ring hangs loosely on a sleeve on the shaft on one side of the bearing and dips into the oil sump in the lower half of the housing. As the shaft rotates, the ring follows and transports oil from the sump to a collecting trough. The oil then flows through the bearing back into the sump. SKF SONL plummer block housings are designed for the oil pick-up ring lubrication method.

For additional information, contact the SKF application engineering service.

### Circulating oil

High-speed operation increases the operating temperature and accelerates ageing of the oil. To avoid frequent oil changes and to achieve a fully flooded lubrication condition, the circulating oil lubrication method is generally preferred (→ **fig. 8**). Circulation is usually controlled by a pump. After the oil has passed through the bearing, it generally settles in a tank where it is filtered and, if required, cooled before being returned to the bearing. Proper filtering decreases the contamination level and extends bearing service life (→ *SKF rating life*, **page 64**). Cooling the oil can also significantly reduce the operating temperature of the bearing.

Fig. 7

Fig. 8

G

## Lubrication

### Oil jet

For very high-speed operation, a sufficient but not excessive amount of oil must be supplied to the bearing to provide adequate lubrication, without increasing the operating temperature more than necessary. One particularly effective method of achieving this is the oil jet method (→ **fig. 9**). A jet of oil under high pressure is directed at the side of the bearing. The velocity of the oil jet must be sufficiently high ( $\geq 15$  m/s) to penetrate the turbulence surrounding the rotating bearing.

### Oil-air

With the oil-air method (→ **fig. 10**) – also called the oil-spot method – compressed air is mixed with very small, accurately metered quantities of oil and directed at each bearing. This minimum quantity lubrication method enables bearings to operate at lower temperatures or at higher speeds than any other lubrication method. The compressed air serves to cool the bearing and also produces an excess pressure in the bearing housing to prevent contaminants from entering.

For additional information about the design of oil-air lubrication arrangements, visit [skf.com/lubrication](http://skf.com/lubrication).

### Oil mist

Oil mist lubrication is not recommended for general applications due to possible negative environmental effects. Today, oil mist lubrication is used in very specific applications such as the petroleum industry.

Fig. 9

Fig. 10

## Lubricating oils

Straight mineral oils are generally the favoured lubricant for lubricating rolling bearings. Oils containing extreme pressure (EP) or anti-wear (AW) additives to improve lubricant properties are generally used only in special cases. The information covering EP and AW additives in grease (→ *Load carrying ability*, page 248) also apply to these additives in oils.

Synthetic versions of many of the popular lubricant classes are available. Synthetic oils are generally only considered for bearing lubrication in extreme cases, e.g. at very low or very high operating temperatures. The term, synthetic oil, covers a wide assortment of different base stocks. The main ones are poly-alphaolefins (PAO), esters and polyalkylene glycols (PAG). These synthetic oils have different properties than mineral oils (→ table 6).

The thickness of the hydrodynamic film, which prevents metal-to-metal contact in a bearing, plays a major role in bearing fatigue life. The thickness of the hydrodynamic film is determined, in part, by the viscosity index (VI) and the pressure-viscosity coefficient. For most mineral oil based lubricants, the pressure-viscosity coefficient is similar, and generic values obtained from literature can be used. However, for synthetic oils, the effect on viscosity to increasing pressure is determined by the chemical structure of its base stock. As a result, there is considerable variation in pressure-viscosity coefficients for different types of synthetic base stocks. Due to the differences in the viscosity index and pressure-

viscosity coefficient, it should be remembered that the formation of a hydrodynamic lubricant film, when using a synthetic oil, may differ from that of a mineral oil with the same viscosity. For additional information about synthetic oils, contact the lubricant supplier.

In addition, additives play a role in the formation of a hydrodynamic film. Due to differences in solubility, different types of additives are used in synthetic oils that are not included in mineral oil based lubricants.

### Selecting lubricating oils

Selecting oil is primarily based on the viscosity required to form a sufficiently thick hydrodynamic film at normal operating temperature. The viscosity of oil is temperature dependent, becoming lower as the temperature rises. The viscosity-temperature relationship of an oil is characterized by the viscosity index (VI). For rolling bearings, oils with a viscosity index of at least 95 (little change with temperature) are recommended.

To form a sufficiently thick oil film in the contact area between the rolling elements and raceways, the oil must retain a minimum viscosity at normal operating temperature. The rated viscosity  $v_1$  required at normal operating temperature to provide adequate lubrication can be determined from **diagram 5** (→ **page 268**), provided a mineral oil is used. When the operating temperature is known from experience or can otherwise be determined, the corresponding viscosity at the internationally standardized reference temperature of 40 °C (105 °F), i.e. the oil ISO VG viscosity class, can be obtained from **diagram 6** (→ **page 269**), which is compiled for a viscosity index of 95.

Certain bearing types, such as spherical roller bearings, toroidal roller bearings, tapered roller bearings, and spherical roller thrust bearings, typically have a higher operating temperature than other bearing types such as ball bearings and cylindrical roller bearings, under comparable operating conditions.

When selecting an oil, consider the following:

- Bearing life may be extended by selecting an oil where the viscosity  $v$  at normal operating temperature is higher than the obtained viscosity  $v_1$  (→ **diagram 5, page 268**). The condition  $v > v_1$  can be obtained by choosing a mineral oil with a higher ISO VG viscosity class or by selecting an oil with a higher viscosity index, provided the oil has the same pressure-viscosity coefficient. Since higher viscosity increases operating temperature, there is frequently a practical limit to the lubrication improvement that can be obtained using this method.

- If the viscosity ratio  $\kappa < 1$  (→ *Viscosity ratio  $\kappa$* , **page 241**), SKF recommends using an oil containing EP additives. If  $\kappa < 0,4$  an oil with EP additives must be used. Oils with EP additives may also enhance operational reliability in cases where  $\kappa > 1$  and medium- and large-size roller bearings are used. It should be remembered that some EP additives may cause adverse effects.
- For exceptionally slow or high speeds, for critical loading conditions, or for unusual lubricating conditions, contact the SKF application engineering service.

### Example

A bearing with a bore diameter  $d = 340$  mm and an outside diameter  $D = 420$  mm is required to rotate at a speed  $n = 500$  r/min. What is the required viscosity  $v$  at the reference temperature of 40 °C (105 °F)?

From **diagram 5** (→ **page 268**) with  $d_m = 0,5(340 + 420) = 380$  mm and  $n = 500$  r/min, the rated viscosity  $v_1$  required for adequate lubrication at normal operating temperature is approximately 11 mm<sup>2</sup>/s. From **diagram 6** (→ **page 269**), assuming that the normal operating temperature is 70 °C (160 °F), a lubricating oil in the ISO VG 32 viscosity class, with an actual viscosity  $v \geq 32$  mm<sup>2</sup>/s at the reference temperature of 40 °C (105 °F), is required.

## Oil change

How frequently oil changes are needed depends mainly on the operating conditions and the quantity of oil.

With the oil bath lubrication method, it is generally sufficient to change the oil once a year, provided the operating temperature does not exceed 50 °C (120 °F) and there is little risk of contamination. Higher temperatures require more frequent oil changes, e.g. for operating temperatures around 100 °C (210 °F), the oil should be changed every three months. Frequent oil changes are also necessary if other operating conditions are arduous.

With circulating oil lubrication systems, the period between oil changes is also determined by how frequently the total oil quantity is circulated and whether or not the oil is cooled. It is only possible to determine a suitable interval through testing and regular inspection to see that the oil is not contaminated or excessively oxidized. The same applies for the oil jet lubrication method. With the oil-air lubrication method, the oil only passes through the bearing once and is not recirculated.

## General

Rolling bearings are reliable machine elements that can provide long service life, provided they are mounted and maintained properly. Proper mounting requires experience, accuracy, a clean work environment and the appropriate tools.

To promote proper installation techniques, speed, accuracy and safety, SKF offers a comprehensive assortment of high quality installation and maintenance products. The assortment includes everything from mechanical and hydraulic tools to bearing heaters and grease. For information about SKF maintenance products, refer to the product information available online at [skf.com/mapro](http://skf.com/mapro).

Mounting bearings correctly is often more difficult than it appears, especially where large bearings are concerned. To be sure that bearings are mounted and maintained properly, SKF offers seminars and hands-on training courses as part of the SKF Reliability Systems concept. Installation and maintenance assistance may also be available from your local SKF company or SKF Authorized Distributor.

The information provided in the following section is quite general and is intended primarily to indicate what must be considered by machine and equipment designers to facilitate bearing mounting and dismounting. For additional information about mounting and dismounting procedures, refer to the *SKF bearing maintenance handbook*.

## Where to mount

Bearings should be mounted in a dry, dust-free area away from machines producing swarf and dust. When bearings have to be mounted in an unprotected area, which is often the case with large bearings, steps should be taken to protect the bearing and mounting position from contaminants like dust, dirt and moisture. This can be done by covering or wrapping bearings, machine components etc. with plastic or foil.

## Preparations prior to mounting or dismounting

Prior to mounting, be sure all the necessary parts, tools, equipment and data are readily available. It is also advisable to review any drawings or instructions to determine the correct order and direction that components are to be assembled. Leave the bearings in their original packages until immediately prior to mounting so that they are not exposed to any contaminants. If there is a risk that the bearings have become contaminated due to improper handling or damaged packaging, they should be washed and dried prior to mounting.

### Checking associated components

Housings, shafts, seals and other components of the bearing system should be checked to make sure that they are clean. This is particularly important for threaded holes, lead-ins or grooves where remnants of previous machining operations might have collected. Also, be sure that all unpainted surfaces of cast housings are free of core sand and that any burrs are removed.

When all components have been cleaned and dried, check the dimensional and form tolerances of each piece. The bearings only perform satisfactorily if the associated components comply with the prescribed tolerances. The diameters of cylindrical shaft and housing seats are usually checked with a micrometer or internal gauge at two cross-sections and in four directions (→ fig. 1). Tapered shaft seats can be checked using a ring gauge (GRA 30 series), a taper gauge (DMB series) or a sine bar (9205 series).

It is advisable to keep a record of all measurements. When measuring, it is important that the components and the measuring instruments are approximately the same temperature. This is particularly important for large bearings and their associated components.

### Removing the preservative

Normally, the preservative applied to new bearings does not need to be removed. It is only necessary to wipe off the outside and bore surfaces. However, if bearings are to be grease lubricated and used at very high or very low temperatures or if the lubricant to be used is not compatible with the preservative, the bearing should be washed and dried carefully. Bearings capped with seals or shields are filled with grease and should not be washed prior to mounting.

When taken from its original packaging, some large bearings with an outside diameter  $D > 420$  mm may be covered with a relatively thick, greasy layer of preservative. These bearings should be washed thoroughly with white mineral spirits or other safe cleaning fluid, and dried.

### Bearing handling

SKF recommends using gloves as well as carrying and lifting tools (→ **fig. 2**) that have been specially designed for handling bearings. Using the proper tools enhances safety while saving time and effort.

When handling hot or oily bearings, SKF recommends wearing the appropriate heat or oil resistant gloves.

For large, heavy bearings, lifting tackle that supports the bearing from the bottom should be used (→ **fig. 3**). A spring between the hook and tackle can facilitate positioning the bearing onto the shaft.

To ease lifting, large bearings can be provided, on request, with threaded holes in the ring side faces to accommodate eye bolts. These holes are designed to accommodate only the weight of the bearing, because the size and depth of the hole is limited by the ring thickness. Make sure that the eye bolts are only subjected to load in the direction of the shank axis (→ **fig. 4**).

When mounting a non-split large housing over a bearing that is already in position on a shaft, it is advisable to provide three-point suspension for the housing, and for the length of one sling to be adjustable. This facilitates the process of aligning the housing bore with the bearing outer ring.

Fig. 2

Fig. 3

Fig. 4

## Mounting

Depending on the bearing type and size, mechanical, thermal or hydraulic methods are used for mounting. In the following, the bearing size is categorized:

- small →  $d \leq 80 \text{ mm}$
- medium-size →  $80 \text{ mm} < d < 200 \text{ mm}$
- large →  $d \geq 200 \text{ mm}$

In all cases, it is important that the bearing rings, cages and rolling elements or seals are never struck directly with any hard object and that the mounting force is never applied through the rolling elements.

For an interference fit, the mating surfaces should be coated with a thin layer of light oil. For a loose fit, the mating surfaces should be coated with SKF anti-fretting agent.

### Mounting bearings with a cylindrical bore

With non-separable bearings, the ring that is to have the tighter fit is usually mounted first.

#### Cold mounting

If the fit is not too tight, small bearings can be driven into position by applying light hammer blows to a sleeve placed against the bearing ring side face. The blows should be evenly distributed around the ring to prevent the bearing from tilting or skewing. The use of a bearing fitting tool (→ fig. 5) or a mounting dolly

(→ fig. 6) instead of a sleeve enables the mounting force to be applied centrally.

Large numbers of bearings are generally mounted with a press.

If a bearing has to be pressed onto the shaft and into the housing bore at the same time, the mounting force must be applied equally to both rings and the abutment surfaces of the mounting tool must lie in the same plane. Whenever possible, mounting should be done with an SKF bearing fitting tool (→ fig. 5).

Fig. 5

Fig. 6

## Mounting, dismounting and bearing care

With self-aligning bearings, the use of an intermediate mounting ring prevents the outer ring from tilting and swiveling when the bearing and shaft assembly is introduced into the housing bore (→ **fig. 7**). The balls of larger self-aligning ball bearings in the 12 and 13 series protrude from the sides of the bearing. This design feature needs to be considered when mounting these bearings.

With separable bearings, the inner ring can be mounted independently of the outer ring, which simplifies mounting, particularly where both rings have an interference fit. When installing the shaft and inner ring assembly into the housing containing the outer ring, careful alignment is required to avoid scoring the raceways and rolling elements. When mounting cylindrical or needle roller bearings with an inner ring without flanges or a flange on one side, a guiding sleeve should be used (→ **fig. 8**). The outside diameter of the sleeve should be the same as the raceway diameter of the inner ring and should be machined to tolerance class  $d10$  (E) for cylindrical roller bearings, and to tolerance  $0/-0,025$  mm for needle roller bearings.

### Hot mounting

It is generally not possible to mount larger bearings without heating either the bearing or the housing, as the force required to mount a bearing increases considerably with increasing bearing size.

The requisite difference in temperature between the bearing ring and shaft or housing depends on the degree of interference and the diameter of the bearing seat. Open bearings must not be heated to more than  $120\text{ }^{\circ}\text{C}$  ( $250\text{ }^{\circ}\text{F}$ ). SKF does not recommend heating bearings capped with seals or shields above  $80\text{ }^{\circ}\text{C}$  ( $175\text{ }^{\circ}\text{F}$ ). However, if higher temperatures are necessary, make sure that the temperature does not exceed the permissible temperature of either the seal or grease, whichever is lowest.

When heating bearings, local overheating must be avoided. To heat bearings evenly, SKF electric induction heaters (→ **fig. 9**) are recommended. If hotplates are used, the bearing must be turned over a number of times. The seals on sealed bearings should never contact the heating plate directly. Place a ring between the plate and bearing.

Fig. 7

Fig. 8

Fig. 9

## Bearing adjustment

The internal clearance of single row angular contact ball bearings and single row tapered roller bearings is only established when the bearing is adjusted against a second bearing. Usually, these bearings are arranged in pairs, either back-to-back or face-to-face, and one bearing ring is axially displaced until a given clearance or preload is obtained. For information about bearing preload, refer to *Bearing preload* (→ page 214).

The following recommendations refer only to the adjustment of the internal clearance for bearing arrangements with angular contact ball bearings or tapered roller bearings.

The appropriate value for the clearance to be obtained when mounting, depends on the bearing size and arrangement and operating conditions such as load and temperature. Since there is a definite relationship between the radial and axial internal clearance of angular contact ball bearings and tapered roller bearings, it is sufficient to specify one value, generally the axial internal clearance. This specified value is then obtained, from a condition of zero clearance by loosening or tightening a nut on the shaft or a threaded ring in the housing bore or by inserting calibrated washers or shims between one of the bearing rings and its abutment. The actual method used to adjust and measure the clearance depends largely on the number of bearings to be mounted.

One way to check the axial clearance in a bearing arrangement is to use a dial indicator attached to the hub (→ fig. 10). When adjusting tapered roller bearings and measuring clearance, the shaft or housing should be turned through several revolutions in both directions to be sure that there is proper contact of the roller ends with the guide flange on the inner ring. Without proper contact, the measured result will not be correct.

Fig. 10

### Mounting bearings with a tapered bore

For bearings with a tapered bore, inner rings are always mounted with an interference fit. The degree of interference is determined by how far the bearing is driven up onto a tapered shaft seat or an adapter or withdrawal sleeve. As the bearing is driven up the tapered seat, its radial internal clearance is reduced. This reduction in clearance or the axial drive-up distance can be measured to determine the degree of interference and the proper fit. Recommended values of clearance reduction and axial drive-up are listed in the relevant product chapter.

#### Small and medium-size bearings

Small and medium-size bearings ( $d \leq 120$  mm) can be driven up onto a tapered seat using either a bearing fitting tool or, preferably, a lock nut. For adapter sleeves, use the sleeve nut that can be tightened with a hook or impact spanner. Withdrawal sleeves can be driven into the bearing bore using a bearing fitting tool or an end plate. Starting from a 50 mm thread, SKF hydraulic nuts can also be used.

#### Medium- and large-size bearings

Because larger bearings ( $d > 120$  mm) require considerably more force to mount, SKF hydraulic nuts should be used. Where applicable, SKF also recommends preparing the shaft for the oil injection method prior to mounting. When combining the two methods, bearing installation and removal becomes much faster, easier and safer. For additional information about the oil injection equipment required for both the hydraulic nut and the oil injection method, refer to the information available online at [skf.com/mapro](http://skf.com/mapro).

#### Mounting with SKF hydraulic nuts

Bearings with a tapered bore can be mounted with the aid of an SKF hydraulic nut:

- on a tapered shaft seat (→ **fig. 11**)
- on an adapter sleeve (→ **fig. 12**)
- on a withdrawal sleeve (→ **fig. 13**)

The hydraulic nut can be positioned onto a threaded section of the shaft (→ **fig. 11**), onto the thread of a sleeve (→ **fig. 12**) or held in place on the shaft by a nut (→ **fig. 13**) or plate

Fig. 11

Fig. 12

Fig. 13

Fig. 14

attached to the end of the shaft. The annular piston abuts the inner ring of the bearing (→ figs. 11 and 12) or the stop on the shaft (→ fig. 13). Pumping oil into the hydraulic nut displaces the piston axially with the force needed for accurate and safe mounting.

#### Oil injection method

With the oil injection method, oil under high pressure is injected via ducts and distribution grooves between the bearing and bearing seat to form an oil film. This oil film separates the mating surfaces and considerably reduces the friction between them. This method is typically used when mounting bearings directly on tapered shaft seats (→ fig. 14). The necessary ducts and grooves should be an integral part of the shaft design. This method can also be used to mount bearings on adapter or withdrawal sleeves if they have been properly prepared.

A spherical roller bearing mounted on a withdrawal sleeve with oil ducts is shown in fig. 15. Oil is injected between all mating surfaces so that the withdrawal sleeve can be pressed into the bearing bore as the bolts are tightened.

Fig. 15

## Mounting, dismounting and bearing care

### Obtaining an interference fit

During mounting, the degree of interference is normally determined by one of the following methods:

- measuring the clearance reduction
- measuring the lock nut tightening angle
- measuring the axial drive-up
- measuring the inner ring expansion

For self-aligning ball bearings, feeling the clearance reduction by swivelling the outer ring is an additional method (→ **page 548**).

### Measuring the clearance reduction

A feeler gauge is most often used to measure the radial internal clearance in medium- and large-size spherical and CARB toroidal roller bearings. Recommended values for the reduction of radial internal clearance to obtain the correct interference fit are listed in the relevant product chapter.

Before mounting, the clearance should be measured between the outer ring and uppermost roller (→ **fig. 16**). After mounting, the clearance should be measured between the inner or outer ring and lowest roller, depending on the bearing internal design (→ **fig. 17**).

Before measuring, the inner or outer ring should be rotated a few times. Both bearing rings and the roller complement must be centrally arranged relative to each other.

For larger bearings, especially those with a thin-walled outer ring, the measurements are affected by the elastic deformation of the rings, caused by the weight of the bearing or the force to draw the feeler gauge blade through the gap between the raceway and an unloaded roller. To establish the “true” clearance before and after mounting, use the following procedure (→ **fig. 18**):

Fig. 16

Fig. 17

Fig. 18

Fig. 19

- 1 Measure the clearance "c" at the 12 o'clock position for a standing bearing or at the 6 o'clock position for an unmounted bearing hanging from the shaft.
- 2 Measure the clearance "a" at the 9 o'clock position and "b" at the 3 o'clock position without moving the bearing.
- 3 Obtain the "true" radial internal clearance with relatively good accuracy from  $0,5(a + b + c)$ .

#### Measuring the lock nut tightening angle

This method can be used for mounting small to medium-size bearings with a tapered bore ( $d \leq 120$  mm). Recommended values for the tightening angle  $\alpha$  are listed in the relevant product chapter.

Before starting the final tightening procedure, the bearing should be pushed up on the tapered seat until it is firmly in position. By tightening the nut through the recommended angle  $\alpha$  (→ **fig. 19**), the bearing is driven up over the proper distance on the tapered seat. The bearing inner ring then has the requisite interference fit. The residual clearance should be checked whenever possible.

H

Fig. 20

#### Measuring the axial drive-up

Mounting bearings with a tapered bore can be done by measuring the axial drive-up of the inner ring on its seat. Recommended values for the required axial drive-up are listed in the relevant product chapter.

However, the SKF Drive-up Method is recommended for medium- and large-size bearings. This method provides a reliable and easy way to determine the degree of interference. The correct fit is achieved by controlling the axial displacement of the bearing from a predetermined position. This method incorporates the use of an SKF hydraulic nut (1) fitted with a dial indicator (2), and a hydraulic pump (3) fitted with a pressure gauge (4), appropriate to the mounting conditions (→ fig. 20).

The SKF Drive-up Method is based on a two stage mounting procedure (→ fig. 21):

Fig. 21

- Stage one  
By applying a predetermined pressure in the hydraulic nut, the bearing is pushed from the "zero" position to a reliable start position.
- Stage two  
By increasing the pressure in the hydraulic nut, the bearing inner ring is pushed further on its tapered seat to the final position. The displacement  $s_s$  is measured by the dial indicator.

Recommended values for the requisite oil pressure to reach the start position and the axial displacement to reach the final position for individual bearings are available online at [skf.com/mount](http://skf.com/mount) or [skf.com/drive-up](http://skf.com/drive-up).

Fig. 22

### Measuring the inner ring expansion

Measuring the inner ring expansion is a quick and accurate method to determine the correct position of large spherical and CARB toroidal roller bearings on their seats ( $d \geq 340$  mm, depending on the series). To take this measurement, use common hydraulic mounting tools and SensorMount, which comprises a bearing with a sensor imbedded in the inner ring and a dedicated hand-held indicator (→ fig. 22). Aspects like bearing size, shaft material and design (solid or hollow), and surface finish do not need any special consideration.

For additional information about SensorMount, contact the SKF application engineering service.

### Test running

Once assembly is complete, an application should undergo a test run to determine that all components are operating properly. During a test run, the application should run under partial load and – where there is a wide speed range – at slow or moderate speeds. A rolling bearing should never be started up unloaded and then accelerated to high speed, as there is a risk that the rolling elements slide and damage the raceways, or that the cage is subjected to impermissible stresses. A minimum bearing load needs to be applied (refer to *Minimum load* in the relevant product chapter).

Any noise or vibration can be checked using an SKF electronic stethoscope. Normally, bearings produce an even “purring” noise. Whistling or screeching indicates inadequate lubrication. An uneven rumbling or hammering is in most cases due to the presence of contaminants in the bearing or to bearing damage caused during mounting.

An increase in bearing temperature immediately after start-up is normal. In the case of grease lubrication, the temperature does not drop until the grease has been evenly distributed in the bearing arrangement, after which an equilibrium temperature is reached. Unusually high temperatures or constant peaking indicate that there is too much lubricant in the arrangement or that the bearing is radially or axially distorted. Other causes could be that associated components have not been made or mounted correctly, or that the seals are generating too much heat.

During the test run, or immediately afterwards, check the seals, any lubrication systems and all fluid levels. If noise and vibration levels are severe, it is advisable to check the lubricant for signs of contamination.

Fig. 23

Fig. 24

Fig. 25

## Dismounting

If bearings are to be used again after removal, the force used to dismount them must never be applied through the rolling elements.

With separable bearings, the ring with the rolling element and cage assembly can be removed independently of the other ring. With non-separable bearings, the ring having the looser fit should be withdrawn from its seat first. To dismount a bearing with an interference fit, the tools described in the following section can be used. The choice of tools depends on the bearing type, size and fit. In the following, the bearing size is categorized:

- small →  $d \leq 80 \text{ mm}$
- medium-size →  $80 \text{ mm} < d < 200 \text{ mm}$
- large →  $d \geq 200 \text{ mm}$

### Dismounting bearings fitted on a cylindrical shaft seat

#### Cold dismounting

Small bearings can be removed from a shaft by applying light hammer blows via a suitable drift to the ring side face, or preferably by using a mechanical puller. The claws must be applied to the inner ring or an adjacent component (→ fig. 23). Dismounting is made easier if slots for the claws of a puller are provided in the shaft and/or housing shoulders. Alternatively, tapped holes in the housing shoulder can be provided to accommodate withdrawal screws (→ fig. 24).

Medium- and large-size bearings generally require greater force than a mechanical tool can provide. Therefore, SKF recommends using either hydraulically assisted tools or the oil injection method, or both. This presupposes that the necessary oil supply ducts and distribution grooves have been designed into the shaft arrangement (→ fig. 25).

## Mounting, dismounting and bearing care

### Hot dismounting

Dismounting with heat is a suitable method when removing inner rings of needle roller bearings or NU, NJ and NUP design cylindrical roller bearings. Two different tools for this purpose are common: heating rings and adjustable induction heaters.

Heating rings are typically used to mount and dismount the inner ring of small to medium-size bearings that are all the same size. Heating rings are made of light alloy. They are radially slotted and equipped with insulated handles (→ **fig. 26**).

If inner rings with different diameters are dismounted frequently, SKF recommends using an adjustable induction heater. These heaters (→ **fig. 27**) heat the inner ring rapidly without heating the shaft.

Special fixed induction heaters have been developed to dismount the inner rings of large cylindrical roller bearings (→ **fig. 28**).

Induction heaters and heating rings are available from SKF. For additional information, visit [skf.com/mapro](http://skf.com/mapro).

Fig. 26

Fig. 27

Fig. 28

### Dismounting bearings fitted on a tapered shaft seat

Small bearings can be dismounted using a mechanical or hydraulically assisted puller that engages the inner ring. Self-centring pullers equipped with spring-operated arms should be used to simplify the procedure and avoid damage to the bearing seat. If it is not possible to apply the claws of the puller to the inner ring, withdraw the bearing via the outer ring or use a puller in combination with a pulling plate (→ **fig. 29**).

Dismounting medium- and large-size bearings is easier and much safer when the oil injection method is used. This method injects oil, under high pressure, between the two tapered mating surfaces, via a supply duct and a distribution groove. This significantly reduces the friction between the two surfaces and produces an axial force that separates the bearing from its seat (→ **fig. 30**).

Fig. 29

Fig. 30

#### WARNING

To avoid the risk of serious injury, attach a provision such as a lock nut to the shaft end to limit bearing travel when the bearing suddenly comes loose.

### Dismounting bearings fitted on an adapter sleeve

Small bearings fitted on an adapter sleeve and a plain shaft can be dismounted by tapping a small steel block with an appropriate hammer evenly around the bearing inner ring side face (→ **fig. 31**). Before doing so, the sleeve lock nut has to be loosened a few turns.

Small bearings fitted on an adapter sleeve and a stepped shaft can be dismounted by a couple of sharp hammer blows applied to a dolly abutting the sleeve lock nut (→ **fig. 32**). Before doing so, the sleeve lock nut has to be loosened a few turns.

Using a hydraulic nut for dismounting bearings fitted on an adapter sleeve and a stepped shaft makes bearing removal easy. To use this method however, it must be possible to mount a suitable stop that abuts to the piston of the hydraulic nut (→ **fig. 33**). If the sleeves are provided with oil supply ducts and distribution grooves, dismounting becomes easier because the oil injection method can be used.

Fig. 32

Fig. 33

### Dismounting bearings fitted on a withdrawal sleeve

When dismounting a bearing fitted on a withdrawal sleeve, the locking device (e.g. lock nut, end plate etc.) has to be removed.

Small and medium-size bearings can be dismounted with a lock nut and a hook or impact spanner (→ **fig. 34**).

Medium- and large-size bearings fitted on a withdrawal sleeve can be easily dismounted with a hydraulic nut. SKF strongly recommends providing a stop behind the hydraulic nut at the shaft end (→ **fig. 35**). The stop prevents the withdrawal sleeve and hydraulic nut from shooting off the shaft if the sleeve separates suddenly from its seat.

Withdrawal sleeves with a bore diameter  $\geq 200$  mm are provided, as standard, with two oil supply ducts and distribution grooves in both the bore and outside surface. When using the oil injection method, two hydraulic pumps and appropriate extension pipes are needed (→ **fig. 36**).

Fig. 34

Fig. 35

Fig. 36

## Bearing storage

The conditions under which bearings, seals and lubricants are stored can have an adverse effect on their performance. Inventory control can also play an important role in performance, particularly if seals and lubricants are involved. Therefore, SKF recommends a “first in, first out” inventory policy.

### Storage conditions

To maximize the service life of bearings, SKF recommends the following basic housekeeping practices:

- Store bearings flat, in a vibration-free, dry area with a cool, steady temperature.
- Control and limit the relative humidity of the storage area as follows:
  - 75% at 20 °C (68 °F)
  - 60% at 22 °C (72 °F)
  - 50% at 25 °C (77 °F)
- Keep bearings in their original unopened packages until immediately prior to mounting to prevent the ingress of contaminants and corrosion.
- Bearings that are not stored in their original packaging should be well protected against corrosion and contaminants.

**NOTE:** Machines on standby should be rotated or run as frequently as possible to redistribute the grease within the bearings and change the position of the rolling elements relative to the raceways.

### Shelf life of open bearings

SKF bearings are coated with a rust-inhibiting compound and suitably packaged before distribution. For open bearings, the preservative provides protection against corrosion for approximately five years, provided the storage conditions are appropriate.

### Shelf life of capped bearings

The maximum storage interval for capped SKF bearings is dictated by the lubricant inside the bearings. Lubricant deteriorates over time as a result of ageing, condensation, and separation of the oil and thickener. Therefore, capped bearings should not be stored for more than three years.

## Inspection and cleaning

As with all other important machine components, rolling bearings must be cleaned and inspected frequently. The intervals between these inspections depend entirely on the operating conditions.

If it is possible to ascertain the condition of a bearing during service, by using condition monitoring equipment, listening to the bearing with a stethoscope, monitoring temperature or lubricant analysis, then it is usually sufficient to clean and inspect all components annually. Where loads are heavy, the frequency of inspection should be increased.

After the bearing components have been cleaned with a suitable solvent such as white mineral spirits, they should be oiled or greased immediately to prevent corrosion. This is particularly important for bearings in machines that are left to stand for extended periods.

## 1 Deep groove ball bearings

### Designs and variants

Deep groove ball bearings are particularly versatile. They are simple in design, non-separable, suitable for high and very high speeds and are robust in operation, requiring little maintenance. Because deep groove ball bearings are the most widely used bearing type, they are available from SKF in many designs, variants and sizes.

In addition to the bearings presented in this chapter, deep groove ball bearings for special applications are shown under *Engineered products*. Deep groove ball bearings for special applications include:

- sensor bearing units (→ **page 1151**)
- bearings for extreme temperatures (→ **page 1169**)
- bearings with Solid Oil (→ **page 1185**)
- SKF DryLube bearings (→ **page 1191**)
- INSOCOAT bearings (→ **page 1205**)
- hybrid bearings (→ **page 1219**)
- NoWear coated bearings (→ **page 1241**)
- polymer ball bearings (→ **page 1247**)

#### Single row deep groove ball bearings

SKF single row deep groove ball bearings (→ **fig. 1**) have deep, uninterrupted raceway grooves. These raceway grooves have a close osculation with the balls, enabling the bearings to accommodate radial loads and axial loads in both directions.

Single row deep groove ball bearings are available open or capped (with seals or shields). Open bearings that are also available capped, may have recesses in the outer ring (→ **fig. 2**).

Inch single row deep groove ball bearings and bearings with a tapered bore are not presented in this catalogue. For information about inch single row deep groove ball bearings, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings). For additional information about deep groove ball bearings with a tapered bore, contact the SKF application engineering service.

#### Stainless steel deep groove ball bearings

SKF stainless steel deep groove ball bearings (→ **fig. 1**) are corrosion resistant when exposed to moisture and several other media. They can accommodate radial loads and axial loads in both directions. These bearings have a lower load carrying capacity than same-sized bearings made of high chromium steel.

The bearings are available open or capped (with seals or shields). Open bearings that are also available capped, may have recesses in

both the inner and outer rings or only in the outer ring (→ **fig. 2**).

Flanged stainless steel deep groove ball bearings and inch bearings are not presented in this catalogue. For information about these bearings, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings).

### Single row deep groove ball bearings with filling slots

Single row deep groove ball bearings with filling slots have a filling slot in both the inner and outer rings (→ **fig. 3**) to accommodate more balls than standard deep groove ball bearings. Filling slot bearings have a higher radial load carrying capacity than bearings without filling slots, but their axial load carrying capacity is limited. They are also unable to operate at the same high speeds as bearings without filling slots.

Deep groove ball bearings with filling slots are available open or with shields. They are also available with or without a snap ring groove. Open bearings that are also available with shields, may have recesses in the outer ring (→ **fig. 4**).

## 1 Deep groove ball bearings

### Double row deep groove ball bearings

SKF double row deep groove ball bearings (→ **fig. 5**) correspond in design to single row deep groove ball bearings. Their deep, uninterrupted raceway grooves have a close osculation with the balls, enabling the bearings to accommodate radial loads and axial loads in both directions.

Double row deep groove ball bearings are very suitable for bearing arrangements where the load carrying capacity of a single row bearing is inadequate. For the same bore and outside diameter, double row bearings are slightly wider than single row bearings in the 62 and 63 series, but have a considerably higher load carrying capacity.

Double row deep groove ball bearings are only available as open bearings (without seals or shields).

### Cages

Depending on their design, series and size, SKF deep groove ball bearings are fitted with one of the cages shown in **table 1**. Double row bearings are equipped with two cages. The standard stamped steel cage is not identified in the bearing designation. If non-standard cages are required, check availability prior to ordering.

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

### Sealing solutions

SKF supplies the most popular sizes of deep groove ball bearings capped with a seal or shield on one or both sides. Selection guidelines for different sealing solutions under various operating conditions are listed in **table 2**. However, these guidelines cannot substitute for testing a seal in its application. For additional information, refer to *Sealing solutions* (→ **page 226**).

ICOS oil sealed bearing units, which are standard deep groove ball bearings with an integrated radial shaft seal, are also available.

When capped bearings must operate under certain extreme conditions, such as very high speeds or high temperatures, grease may leak at the inner ring. For bearing arrangements where this would be detrimental, special design steps must be undertaken. For additional information, contact the SKF application engineering service.

Bearings capped on both sides are lubricated for the life of the bearing and should not be washed or relubricated. They are filled with the appropriate amount of a high-quality grease under clean conditions. The bearings are considered maintenance-free. If they are to be hot mounted, an induction heater should be used.

SKF does not recommend heating capped bearings above 80 °C (175 °F). However, if higher temperatures are necessary, make sure that the temperature does not exceed the permissible temperature of either the seal or grease, whichever is lowest.

The seals, which are fitted in a recess on the outer ring, make good, positive contact with the recess, without deforming the outer ring (→ **figs. 7 to 9, pages 301 to 303**).

## Shields

Bearings with shields are primarily intended for applications where the inner ring rotates. Shields are fitted in the outer ring and do not make contact with the inner ring, but form a narrow gap with it. Shields are made of sheet steel. For stainless steel bearings, stainless steel is used.

Depending on the bearing design, series and size, SKF supplies shields in different designs. Shields identified by the designation suffix Z typically have an extension in the shield bore to form a long, narrow gap with the land of the inner ring shoulder (→ **fig. 6a**). Some shields do not have the extension (→ **fig. 6b**). The bore of a Z shield on some stainless steel deep groove ball bearings can extend into a recess on the inner ring (→ **fig. 6c**).

Shields identified by the designation suffix ZS are available for stainless steel bearings only. These shields are fixed in the outer ring by a retaining ring (→ **fig. 6d**) and may extend into a recess on the inner ring.

## Non-contact seals

Bearings with non-contact seals can be operated at the same speeds as bearings with shields, but with improved sealing effectiveness. The seals form an extremely narrow gap with the land of the inner ring shoulder (→ **fig. 7**). Non-contact seals are made of oil and wear-resistant NBR that is reinforced by a sheet steel insert.

SKF deep groove ball bearings with a non-contact seal on one or both sides are identified

by the designation suffix RZ or 2RZ. Non-contact seals are available for single row deep groove ball bearings only.

Some stainless steel bearings are available with non-contact seals on request. The exact seal design may differ from the illustration (→ **fig. 7**).

## 1 Deep groove ball bearings

### Low-friction seals

Bearings with low-friction seals can accommodate the same speeds as bearings with shields, but with improved sealing effectiveness. The seals are practically non-contacting with a recess in the inner ring shoulder.

Single row deep groove ball bearings with a low-friction seal on one or both sides are identified by the designation suffix RSL or 2RSL. The seals are made of oil and wear-resistant NBR that is reinforced with a sheet steel insert.

Low-friction seals are available for bearings in the 60, 62 and 63 series. They are manufactured in two designs depending on bearing size (→ **fig. 8**).

### Contact seals

Contact seals (→ **fig. 9**) are made of oil and wear-resistant NBR or FKM and are reinforced with a sheet steel insert.

SKF deep groove ball bearings with a contact seal made of NBR on one or both sides are manufactured in five designs depending on the bearing:

- Bearings in the 60, 62, and 63 series are equipped with RSH seals to design **(a)** when  $D \leq 25$  mm.
- Bearings in the 60, 62 and 63 series are equipped with RSH seals to design **(b)** when  $25 \text{ mm} < D \leq 52$  mm.
- Other bearings have RS1 seals, which seal against the land of the inner ring shoulder **(c)** or against a recess in the inner ring side face **(d)**. The difference is indicated by dimension  $d_1$  or  $d_2$  in the product tables.
- Stainless steel bearings are equipped with RS1 seals to design **(c)** or **(e)**. The exact seal design may differ from the illustrations.

Bearings with seals made of FKM are available on request. They are identified by the designation suffix RS2 or 2RS2.

### WARNING

Seals made of FKM (fluoro rubber) exposed to an open flame or temperatures above  $300 \text{ }^\circ\text{C}$  ( $570 \text{ }^\circ\text{F}$ ) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions under *Seal materials* (→ **page 155**).

## 1 Deep groove ball bearings

### ICOS oil sealed bearing units

ICOS oil sealed bearing units are designed for applications where sealing requirements exceed the capabilities of bearings with contact seals. An ICOS unit consists of a 62 series deep groove ball bearing and one integral SKF WAVE seal (→ **fig. 10**). The SKF WAVE seal is a single lip, spring loaded radial shaft seal made of NBR. ICOS units need less axial space than an arrangement using a bearing and an external seal. They simplify mounting and avoid expensive machining of the shaft because the inner ring shoulder is the seal counterface.

The limiting speeds quoted in the product table are based on the permissible circumferential speed for the seal, which is 14 m/s.

### Greases for capped bearings

Depending on the design, series and size, bearings capped on both sides are filled with one of the following standard greases:

- basic design deep groove ball bearings → **table 3**
- SKF Energy Efficient deep groove ball bearings → low-friction grease GE2
- stainless steel deep groove ball bearings → LHT23
- deep groove ball bearings with filling slots → GJN.

Fig. 10

On request, bearings can be supplied with the following special greases:

- high temperature grease GJN when  $D \leq 62$  mm
- wide temperature range grease HT or WT
- wide temperature range and silent running grease LHT23 (for bearings where it is not standard)
- low temperature grease LT
- non-toxic grease (designation suffix VT378) for stainless steel deep groove ball bearings

This grease fulfils the requirements of the "Guidelines of section 21 CFR 178.3570" of the FDA (US Food and Drug Administration) regulations and is approved by the USDA (United States Department of Agriculture) for category H1 use (lubricants with incidental food contact).

Table 3

The technical specifications of the various greases are listed in **table 4**. The standard grease is not identified in the bearing designation (no designation suffix). Special greases are indicated by the corresponding grease suffix. Check availability of bearings with special grease prior to ordering.

## Grease life for capped bearings

Grease life for capped bearings should be estimated according to the procedure described in this section. The grease life for capped bearings is presented as  $L_{10}$ , i.e. the time period at the end of which 90% of the bearings are still reliably lubricated. The method to estimate relubrication intervals (→ *Relubrication intervals*, page 252) represents the  $L_{01}$  grease life and should not be used.

The grease life for capped bearings depends on the operating temperature and the speed factor. It can be obtained from the diagrams.

**Diagram 1** is valid for standard deep groove ball bearings. The grease performance factor (GPF) is listed in **table 4** (→ page 305).

**Diagram 2** is valid for SKF Energy Efficient deep groove ball bearings.

The grease life for each is valid under the following operating conditions:

- horizontal shaft
- inner ring rotation
- light load ( $P \leq 0,05 C$ )
- operating temperature within the green temperature zone of the grease (→ **table 4, page 305**)
- stationary machine
- low vibration levels

For stainless steel bearings filled with VT378 grease, use the scale corresponding to  $GPF = 1$  and multiply the value obtained from the diagram by 0,2.

Diagram 1

Grease life for capped deep groove ball bearings  
where  $P = 0,05 C$

$n$  = rotational speed [r/min]  
 $d_m$  = bearing mean diameter [mm]  
 $= 0,5 (d + D)$

If the operating conditions differ, the grease life obtained from the diagrams has to be adjusted:

- For vertical shafts, use 50% of the value from the diagram.
- For heavier loads ( $P > 0,05 C$ ), use the reduction factor listed in **table 5**.

Table 5

Reduction factor for the grease life, depending on the load

## 1 Deep groove ball bearings

### Bearings with a snap ring groove

Deep groove ball bearings with a snap ring groove can simplify the design of an arrangement because the bearings can be located axially in the housing by a snap ring (→ **fig. 11**). This saves space and can significantly reduce installation time. Appropriate snap rings are shown in the product tables with their designation and dimensions. They can be supplied separately or fitted to the bearing.

The following variants (→ **fig. 12**) are available for basic design deep groove ball bearings and for bearings with filling slots:

- open bearings with a snap ring groove only (designation suffix N)
- open bearings with a snap ring (designation suffix NR)
- bearings with a snap ring and a shield on the opposite side (designation suffix ZNR)
- bearings with a snap ring and a shield on both sides (designation suffix 2ZNR)

For bearings with filling slots, the snap ring groove is on the same side as the filling slots.

### Quiet running bearings

SKF Quiet Running deep groove ball bearings are designed to comply with stringent noise requirements in applications such as wind turbine generators and to provide consistent performance over a variety of operating conditions. These bearings are identified by the designation suffix VQ658. The range covers bearing sizes typically used in wind turbine generators. For additional information, contact the SKF application engineering service.

### Matched bearings

For bearing arrangements where the load carrying capacity of a single bearing is inadequate, or where the shaft has to be located axially in both directions with a specific axial clearance, SKF can supply matched pairs of single row deep groove ball bearings on request. Depending on the requirements, the matched pairs can be supplied in tandem, back-to-back, or face-to-face arrangements (→ fig. 13). The bearings are matched in production so that, when mounted immediately adjacent to each other, the load is evenly distributed between the bearings without having to use shims or similar devices.

For additional information about matched bearings, refer to the product information available online at [skf.com/bearings](https://skf.com/bearings).

Fig. 13

### Performance classes

#### SKF Explorer bearings

In response to the ever-demanding performance requirements of modern machinery, SKF developed the SKF Explorer performance class of rolling bearings.

SKF Explorer deep groove ball bearings realized this substantial improvement in performance by optimizing the internal geometry and surface finish of all contact surfaces, redesigning the cage, combining the extremely clean and homogenous steel with a unique heat treatment and improving the quality and consistency of the balls.

SKF Explorer deep groove ball bearings provide superior performance especially in applications like electric motors, two-wheelers and transmissions. These improvements provide the following benefits:

- higher dynamic load carrying capacity
- reduced noise and vibration levels
- less frictional heat
- significantly extended bearing service life

These bearings reduce environmental impact by enabling downsizing and reducing both lubricant and energy consumption. Just as importantly, SKF Explorer bearings can reduce the need for maintenance and contribute to increased productivity.

SKF Explorer bearings are shown with an asterisk in the product tables. The bearings retain the designation of earlier standard bearings. However, each bearing and its box are marked with the name “SKF EXPLORER”.

#### SKF Energy Efficient (E2) bearings

To meet the ever-increasing demand to reduce friction and energy consumption, SKF has developed the SKF Energy Efficient (E2) performance class of rolling bearings. SKF E2 deep groove ball bearings are characterized by a frictional moment in the bearing that is at least 30% lower when compared to a same-sized SKF Explorer bearing.

The bearings realized the substantial reduction of the frictional moment by optimizing the internal geometry of the bearing, redesigning the cage and applying a new, low-friction grease.

SKF E2 deep groove ball bearings have been shown to last longer and consume less lubricant than comparable SKF Explorer deep groove ball bearings. The enhanced performance characteristics require the following conditions:

- speed  $n > 1\,000$  r/min
- load  $P \leq 0,125 C$

If conditions vary, contact the SKF application engineering service.

Typical applications include electric motors, pumps, conveyors and fans.

SKF E2 deep groove ball bearings are available in the 60, 62 and 63 dimension series. They are supplied with a shield on both sides and have C3 radial internal clearance as standard.

Calculation factors must be selected according to the operating clearance in the bearing, which may differ from the internal clearance before mounting. For additional information or for calculation factors for other clearance classes, contact the SKF application engineering service.

Intermediate values can be obtained by linear interpolation.

## 1 Deep groove ball bearings

### Temperature limits

The permissible operating temperature for deep groove ball bearings can be limited by:

- the dimensional stability of the bearing rings and balls
- the cage
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

#### Bearing rings and balls

SKF deep groove ball bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 120 °C (250 °F).

#### Cages

Steel or brass cages can be used at the same operating temperatures as the bearing rings and balls. For temperature limits of polymer cages, refer to *Cage materials* (→ **page 152**).

#### Seals

The permissible operating temperature for seals depends on the material:

- NBR seals:  
–40 to +100 °C (–40 to +210 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- FKM seals:  
–30 to +230 °C (–20 to +445 °F)

#### Lubricants

Temperature limits for greases used in SKF deep groove ball bearings capped on both sides are provided in **table 4** (→ **page 305**). Temperature limits for other SKF greases are provided under *Lubrication* (→ **page 239**).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

### Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**). If no reference speed is listed in the product tables, the limiting speed is the permissible speed.

SKF recommends oil lubrication for bearings with a ring centred cage (designation suffix MA or MB). When these bearings are grease lubricated (→ *Lubrication*, **page 239**) the speed factor is limited to  $A \leq 450\,000$  mm/min.

where

$$A = n \cdot d_m \text{ [mm/min]}$$

$$d_m = \text{bearing mean diameter [mm]} \\ = 0,5 (d + D)$$

$$n = \text{rotational speed [r/min]}$$

For applications exceeding these values, contact the SKF application engineering service.

#### Matched bearings

For matched bearings, the permissible speed calculated for a single bearing should be reduced to approximately 80% of the quoted value.

### Suffixes

#### Group 1: Internal design

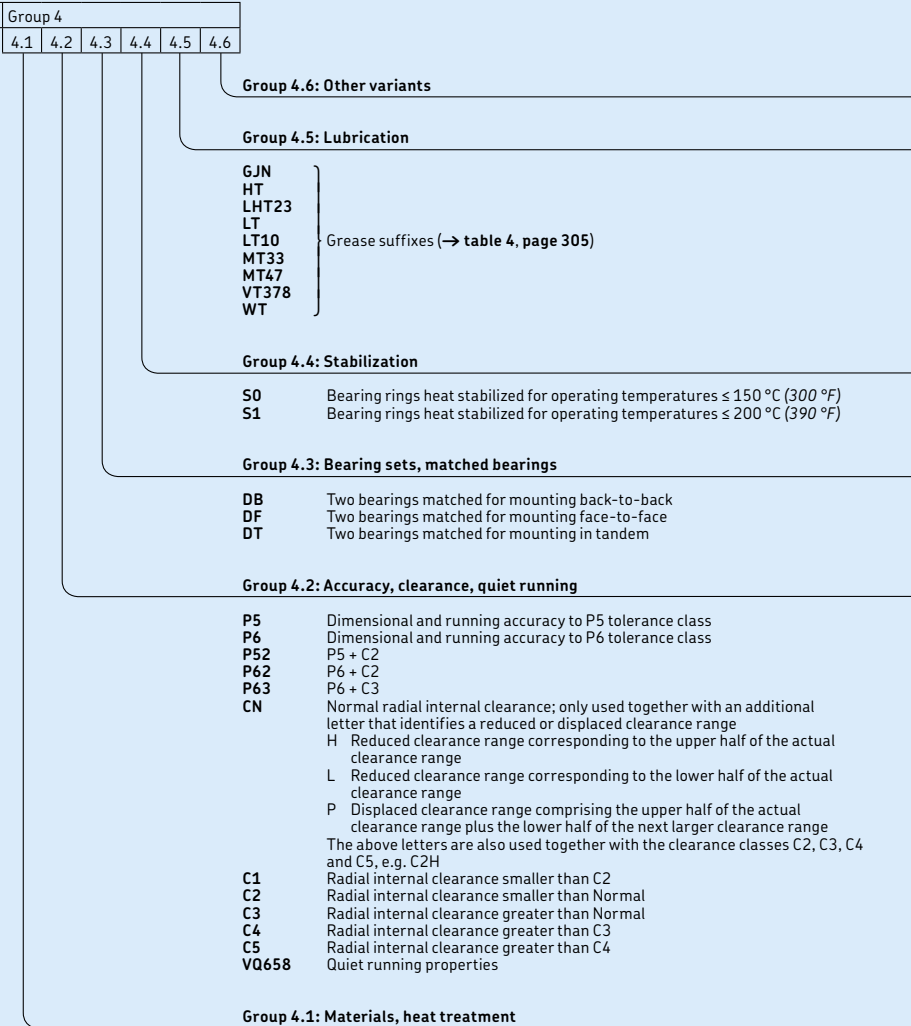

<b>E</b>	Reinforced ball set
----------	---------------------

#### Group 2: External design (seals, snap ring groove etc.)

<b>N</b>	Snap ring groove in the outer ring
<b>NR</b>	Snap ring groove in the outer ring, with appropriate snap ring
<b>N1</b>	One locating slot (notch) in one outer ring side face
<b>R</b>	Flanged outer ring
<b>-RS1, -2RS1</b>	Contact seal, NBR, on one or both sides
<b>-RS2, -2RS2</b>	Contact seal, FKM, on one or both sides
<b>-RSH, -2RSH</b>	Contact seal, NBR, on one or both sides
<b>-RSL, -2RSL</b>	Low-friction seal, NBR, on one or both sides
<b>-RZ, -2RZ</b>	Non-contact seal, NBR, on one or both sides
<b>-Z, -2Z</b>	Shield on one or both sides
<b>-ZNR</b>	Shield on one side, snap ring groove in the outer ring, snap ring on the opposite side of the shield
<b>-ZZNR</b>	Shield on both sides, snap ring groove in the outer ring, with snap ring
<b>-ZZS</b>	Shield on both sides, held in place by a retaining ring
<b>X</b>	Boundary dimensions not in accordance with ISO dimension series

#### Group 3: Cage design

<b>-</b>	Stamped steel cage, ball centred
<b>M</b>	Machined brass cage, ball centred; different designs or material grades are identified by a number following the M, e.g. M2
<b>MA(S)</b>	Machined brass cage, outer ring centred. The S indicates a lubrication groove in the guiding surface.
<b>MB(S)</b>	Machined brass cage, inner ring centred. The S indicates a lubrication groove in the guiding surface.
<b>TN9</b>	Glass fibre reinforced PA66 cage, ball centred
<b>TNH</b>	Glass fibre reinforced PEEK cage, ball centred
<b>VG1561</b>	Glass fibre reinforced PA46 cage, ball centred

## Designs and variants

Y-bearings (insert bearings) are based on sealed deep groove ball bearings in the 62 and 63 series. Y-bearings typically have a sphered (convex) outside surface and an extended inner ring (→ **fig. 1**) with different locking devices to enable quick and easy mounting onto the shaft. The various Y-bearing series differ in the way the bearing is locked onto the shaft:

- with grub (set) screws (→ **fig. 2**)
- with an eccentric locking collar (→ **fig. 3**)
- with SKF ConCentra locking technology (→ **fig. 4**)
- with an adapter sleeve (→ **fig. 5**)
- with an interference fit (→ **fig. 6**)

The standard SKF Y-bearing assortment includes application specific variants:

- bearings made of stainless steel or with zinc-coated rings for the food industry (→ **page 424**)
- bearings for agricultural applications (→ **page 435**)
- bearings for extreme temperatures (→ **page 1169**)
- bearings with Solid Oil (→ **page 1185**)
- SKF DryLube bearings (→ **page 1191**)

Other variants are available on request. These include Y-bearings with:

- a cylindrical outer ring
- a customized design or dimensions
- a hexagonal or square bore
- a special cage
- special grease and special grease quantity
- a special coating

For additional information about these variants, contact the SKF application engineering service.

### Y-bearing units

SKF also supplies a wide variety of Y-bearing units, but are not listed in this rolling bearing catalogue. For information about Y-bearing units, refer to the SKF catalogue *Y-bearings and Y-bearing units* or the product information available online at [skf.com/bearings](http://skf.com/bearings).

## 2 Y-bearings

### Y-bearings with grub screws

Y-bearings with grub (set) screws in the inner ring are locked onto the shaft by tightening the two cup point hexagonal grub screws, positioned 120° apart. These bearings are suitable for applications for both constant and alternating direction of rotation.

#### Basic design bearings

Two different basic design Y-bearings with grub screws are available.

Y-bearings in the YAT 2 series (→ **fig. 7**) have an inner ring extended on one side.

Y-bearings in the YAR 2 series (→ **fig. 8**) have an inner ring extended on both sides. This reduces the extent to which the inner ring can tilt on the shaft, which enables the bearing to run more smoothly.

Bearings in both the YAT 2 and YAR 2 series are fitted with a rugged standard seal (→ *Standard seals*, **page 429**) and a flinger on both sides. Flinger options are:

- a plain sheet steel flinger, designation suffix 2F
- a rubberized sheet steel flinger (multiple seal), designation suffix 2RF

Y-bearings in the YAT 2 and YAR 2 series have two lubrication holes in the outer ring as standard, one on each side, positioned 120° apart. Bearings without lubrication holes can be supplied on request (designation suffix W).

SKF YAT 2 and YAR 2 series bearings are available for metric shafts from 12 to 100 mm and for inch shafts from 1/2 to 3 inches.

#### Bearings with zinc-coated rings

Y-bearings with an inner ring extended on both sides are also available with zinc-coated rings for use in corrosive environments. Bearings in the YAR 2..-2RF/VE495 series are fitted with a highly effective multiple seal (→ *Multiple seals*, **page 429**) made of food-compatible rubber with a stainless steel insert and a stainless steel flinger on both sides. The grub screws are made of stainless steel. The bearings are filled with a food-grade grease and can be relubricated through one of the two lubrication holes in the outer ring. The lubrication holes are positioned 120° apart, one on each side.

SKF Y-bearings with zinc-coated rings are available for metric shafts from 20 to 50 mm and for inch shafts from 3/4 to 1 15/16 inches.

#### Stainless steel bearings

All steel components of these bearings are made of stainless steel, including rings, balls, sheet metal parts of both seals and flingers, and grub screws. The inner ring is extended on both sides. Bearings in the YAR 2..-2RF/HV series are fitted with a highly effective multiple seal (→ *Multiple seals*, **page 429**) made of food-compatible rubber with a stainless steel insert and a stainless steel flinger on both sides. They are filled with a food-grade grease and can be relubricated through the lubrication

hole in the outer ring groove. This lubrication groove is located on the side opposite the locking device.

The dynamic load carrying capacity of a stainless steel bearing is less than that of a same-sized bearing made of high grade carbon chromium steel.

SKF stainless steel Y-bearings are available for metric shafts from 20 to 50 mm and for inch shafts from  $\frac{3}{4}$  to  $1\frac{15}{16}$  inches.

### Y-bearings with an eccentric locking collar

Y-bearings with an eccentric locking collar are intended primarily for use in applications where the direction of rotation is constant. On one side, the extended inner ring of the bearing has an eccentric step. The step accommodates the locking collar. Turning the locking collar in the direction of rotation locks the collar and bearing onto the shaft. A single grub screw further secures the collar to the shaft. The eccentric collar is zinc-coated for bearings with a metric bore and black oxidized for bearings with an inch bore. There are two standard series available from SKF.

Y-bearings in the YET 2 series have an inner ring extended on one side (→ **fig. 9**).

Y-bearings in the YEL 2 series have an inner ring extended on both sides (→ **fig. 10**). This reduces the extent to which the inner ring can tilt on the shaft, which enables the bearing to run more smoothly.

Bearings in both the YET2 and YEL 2 series are fitted with a rugged standard seal (→ *Standard seals*, **page 429**) and a flinger on both sides. Flinger options are:

- a plain sheet steel flinger, designation suffix 2F
- a rubberized sheet steel flinger (multiple seal), designation suffix 2RF/VL065

Y-bearings in the YET 2 and YEL 2 series have two lubrication holes in the outer ring as standard, one on each side, positioned  $120^\circ$  apart. Bearings without lubrication holes can be supplied on request (designation suffix W).

SKF Y-bearings with an eccentric locking collar are available for metric shafts from 15 to 60 mm and for inch shafts from  $\frac{1}{2}$  to  $2\frac{7}{16}$  inches.

Fig. 9

Fig. 10

## 2 Y-bearings

### SKF ConCentra Y-bearings

SKF ConCentra Y-bearings have an inner ring symmetrically extended on both sides (→ **fig. 11**). The patented SKF ConCentra locking technology is based on the expansion and contraction of two mating surfaces: the bearing bore and the external surface of the stepped sleeve. Both surfaces have precision-engineered serrations. When the grub screws in the mounting collar are tightened, the inner ring is displaced axially, relative to the stepped sleeve (→ **fig. 12**). This forces the bearing inner ring to expand and the stepped sleeve to contract evenly, providing a true concentric fit on the shaft. SKF ConCentra Y-bearings provide an easy, quick and reliable way to lock a bearing onto a shaft.

The true concentric fit on the shaft provides low noise and vibration levels and virtually eliminates fretting corrosion. Even more important is that the fit on the shaft does not loosen, even in applications where there are heavy loads and/or high speeds. The shaft tolerance does not limit the permissible bearing speed and the full limiting speed can be achieved, even when using commercial grade shafts. The bearings can be used in applications for both constant and alternating direction of rotation.

SKF ConCentra Y-bearings, series designation YSP 2, are equipped with a rugged standard seal on both sides, fitted with additional plain sheet steel flingers (→ *Standard seals with additional flingers*, **page 429**). The outer ring has two lubrication holes as standard, one

Fig. 11

on each side, positioned 120° apart. Bearings without lubrication holes can be supplied on request (designation suffix W).

SKF Y-bearings in the YSP 2 series are available for metric shafts from 25 to 60 mm and for inch shafts from 1 to 2 <sup>11</sup>/<sub>16</sub> inches.

Fig. 12

### Y-bearings with a tapered bore

Y-bearings with a tapered bore (→ **fig. 13**) have an inner ring symmetrically extended on both sides and a tapered bore (taper 1:12) enabling them to be mounted on a standard H 23 series adapter sleeve. Mounting onto an adapter sleeve enables the bearings to run smoothly and the full limiting speed can be achieved, even when using commercial grade shafts. The bearings can be used in applications for both constant and alternating direction of rotation. The appropriate adapter sleeve is not part of the bearing and must be ordered separately.

Y-bearings with a tapered bore, series designation YSA 2, are equipped with a rugged standard seal, fitted with an additional plain sheet steel flinger on both sides (→ *Standard seals with additional flingers*, **page 429**). The outer ring has two lubrication holes as standard, one on each side, positioned 120° apart. Bearings without lubrication holes can be supplied on request (designation suffix W).

SKF Y-bearings in the YSA 2 series are available with bore diameters ranging from 25 to 65 mm, which fit adapter sleeves in the H 23 series for metric shafts ranging from 20 to 60 mm. These bearings can also be used on adapter sleeves in the HA 23, HE 23 and HS 23 series for inch shafts ranging from  $\frac{3}{4}$  to  $2\frac{3}{8}$  inches.

Fig. 13

## 2 Y-bearings

### Y-bearings with a standard inner ring

Y-bearings with a standard inner ring (→ **fig. 14**) have normal tolerances for the bearing bore diameter and are locked onto the shaft using an appropriate interference fit. These bearings in the 17262 and 17263 series have the same dimensions and features as deep groove ball bearings in the 62 and 63 series, but have a sphered (convex) outside surface. The bearings are suitable for applications where the direction of the load alternates and where smooth running is a key operational parameter. They can accommodate heavier axial loads than any other Y-bearings and can operate at the same speeds as a corresponding sealed deep groove ball bearing. They do not have any lubrication holes in the outer ring.

SKF Y-bearings with a standard inner ring are available for metric shafts from 17 to 60 mm.

### Cages

Y-bearings are fitted as standard with a snap-type, glass fibre reinforced PA66 cage (→ **fig. 15**), no designation suffix.

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

Fig. 14

Fig. 15

## Sealing solutions

SKF supplies all Y-bearings capped with a seal or shield on both sides. In typical Y-bearing applications, no additional external protection is necessary. Therefore, Y-bearings are available with several sealing arrangement designs to meet the demands of a wide range of operating conditions.

### Standard seals

The standard seals for Y-bearings (no designation suffix) consist of a stamped sheet steel washer with a seal lip made of NBR, vulcanized to its inner surface (→ **fig. 16**). The non-contact sheet steel washer forms a narrow gap with the cylindrical surface of the inner ring shoulder and protects the land-riding seal against coarse contaminants.

### Standard seals with additional flingers

For more contaminated environments, SKF recommends Y-bearings equipped with a standard seal and an additional plain flinger on both sides (→ **fig. 17**, designation suffix 2F). The flinger, made of sheet steel or stainless sheet steel, has an interference fit on the inner ring to considerably improve the effectiveness of the seal without increasing friction. These seals are only available for bearings with an inner ring extended on both sides.

### Multiple seals

For very contaminated environments, SKF recommends Y-bearings equipped with the highly effective multiple seal on both sides (→ **fig. 18**, designation suffix 2RF). This sealing arrangement consists of a standard seal and a flinger with a vulcanized NBR lip. The flinger lip seals axially against the standard seal. The space between the flinger lip and the shaft is filled with grease to provide additional protection. These seals are only available for bearings with an inner ring extended on both sides.

Fig. 16

Fig. 17

Fig. 18

## 2 Y-bearings

### 5-lip seals

For extremely contaminated environments, such as agricultural applications, SKF recommends Y-bearings equipped with the patented 5-lip seal on both sides (→ **fig. 19**). The seal consists of a sheet steel insert with a vulcanized 5-lip contact seal made of a low-friction NBR compound. The steel insert, which protects the bearing from solid contaminants, is held in place by a groove in the bearing outer ring. Each seal lip has a different design to provide superior sealing performance in response to different operating conditions, including dynamic misalignment. The outermost and innermost lips act as a labyrinth to prevent contaminant ingress and grease leakage respectively. The three inner lips make constant contact with the inner ring shoulder.

### Seals for SKF Energy Efficient Y-bearings

These seals minimize the frictional moment in SKF Energy Efficient Y-bearings while providing effective protection in less contaminated environments. The seals are made of NBR and are sheet steel reinforced. The lip has an innovative thin and flexible design (→ **fig. 20**). They are fitted in a recess on the outer ring and seal against the inner ring shoulder. The sheet steel insert protects against solid contaminants.

Depending on the bearing series, the sealing effect can be enhanced by adding plain sheet steel flingers (designation suffix 2F). The flingers have an interference fit on the inner ring and do not increase friction.

### RS1 seals

Y-bearings with a standard inner ring are equipped with an RS1 seal on both sides. These NBR contact seals, developed for standard SKF deep groove ball bearings, are reinforced with a sheet steel insert (→ **fig. 21**, designation suffix 2RS1). They are fitted in a recess on the outer ring and ride against the inner ring shoulder.

Fig. 19

Fig. 20

Fig. 21

## Shields

On request, Y-bearings can be supplied with a shield on both sides. The sheet steel shields are fitted in a recess on the outer ring and do not make contact with the inner ring, but form a narrow gap (→ **fig. 22**, designation suffix VP076). They are designed for applications where the contamination level is low and additional friction should be avoided. Bearings with shields should not be used if water, steam or moisture can enter the bearing.

Fig. 22

## Greases for capped bearings

Y-bearings are filled with one of the following greases:

- SKF Energy Efficient Y-bearings  
→ low-friction grease GE2
- zinc-coated and stainless steel Y-bearings  
→ food-grade grease GFJ  
This grease fulfils the requirements listed in the Guidelines of section 21 CFR 178.3570 of the FDA (US Food and Drug Administration) regulations. It is approved by the USDA (United States Department of Agriculture) for Category H1 use (occasional contact with food stuffs).
- all other Y-bearings  
→ standard grease VT307

The technical specifications for the various greases are listed in **table 1**.

## 2 Y-bearings

### Grease life for Y-bearings

Grease life for Y-bearings should be estimated according to the procedure described in this section. The grease life for Y-bearings is presented as  $L_{10}$ , i.e. the time period at the end of which 90% of the bearings are still reliably lubricated. The method to estimate relubrication intervals (→ *Relubrication intervals*, **page 252**) represents the  $L_{01}$  grease life and should not be used.

The grease life for Y-bearings depends on the operating temperature and the speed factor. It can be obtained from the diagrams.

**Diagram 1** is valid for Y-bearings filled with VT307 grease or GFJ food-grade grease.

**Diagram 2** is valid for SKF Energy Efficient Y-bearings.

The grease life for each is valid under the following operating conditions:

- horizontal shaft
- very light to moderate loads ( $P \leq 0,05 C$ )
- stationary machine
- low vibration levels

If operating conditions differ, the grease life obtained from the diagrams has to be adjusted:

- For vertical shafts, use 50% of the value from the diagram.
- For heavier loads ( $P > 0,05 C$ ), use the reduction factor listed in **table 3**.

The values for adjusting the grease life are estimates. Vibration can have a negative influence on grease life. The extent cannot be quantified, and the influence increases with increasing operating temperature. For additional information, refer to *Lubrication* (→ **page 239**) or contact the SKF application engineering service.

## 2 Y-bearings

### Relubrication

Y-bearings do not need relubrication when the grease life (→ *Grease life for Y-bearings*, **page 432**) exceeds the SKF rating life of the bearing (→ *Selecting bearing size*, **page 61**).

Relubrication can extend bearing service life under any of the following conditions:

- The bearings are exposed to high humidity or severe contamination.
- The bearings accommodate normal or heavy loads.
- The bearings operate for extended periods at high speeds or at temperatures above 55 °C (130 °F), above 75 °C (170 °F) for SKF Energy Efficient Y-bearings.
- The bearings are subjected to high vibration levels.

To relubricate Y-bearings, the following greases can be used:

- SKF Energy Efficient Y-bearings  
→ exclusively low-friction grease SKF LEGE 2
- zinc-coated and stainless steel Y-bearings  
→ food-grade grease SKF LGFP 2
- all other Y-bearings  
→ SKF LGWA 2, LGMT 2 or LGMT 3 grease

If relubrication is needed, the relubrication intervals can be estimated following the method explained under *Lubrication* (→ **page 239**)

When relubricating, the shaft should be turned and grease should be pumped slowly until fresh grease starts to escape from the seal(s). Excessive pressure from pumping too quickly can damage the seals. When machines and equipment are used for a limited period of time, SKF recommends relubricating each bearing at the end of the operational period, i.e. immediately before being laid up.

### Relubrication features

SKF Y-bearings are designed to facilitate relubrication. They have two lubrication holes in the outer ring as standard, one on each side, positioned 120° apart. Bearings without lubrication holes can be supplied on request (designation suffix W).

The following bearings do not have the standard relubrication features:

- Stainless steel Y-bearings with grub screws have a lubrication groove in the outer ring located on the side opposite the locking device and one lubrication hole within this groove.
- Y-bearings with a standard inner ring and Y-bearings for agricultural applications are lubricated for life and cannot be relubricated. They do not have any lubrication holes.

## Y-bearings for agricultural applications

Y-bearings for agricultural applications are designed to withstand the demanding operating conditions that occur in machinery like combines and balers, harvesters and disk harrows. Extensive laboratory tests and field experience confirm that these bearings outlast conventional bearings, which typically have a one to three year life span.

Y-bearings for agricultural applications are equipped with a patented 5-lip seal on both sides (→ [page 430](#)). The bearings are lubricated for life with VT307 grease (→ [table 1, page 431](#)). The grease has a high resistance to water washout, enabling long bearing service life in wet environments. The bearings cannot be relubricated.

Y-bearings for agricultural applications are dimensionally interchangeable with standard Y-bearings, enabling easy upgrades of existing applications to reduce machine downtime and environmental impact. SKF Y-bearings for agricultural applications are available for metric shafts from 20 to 50 mm and for inch shafts from 1 to 1 <sup>15</sup>/<sub>16</sub> inches. The bearings are available with three different locking methods (→ [fig. 23](#)):

- Y-bearings in the YARAG 2 series, which are interchangeable with bearings in the YAR 2 series, are locked onto the shaft with two grub screws. They are typically used for moderate loads.
- Y-bearings in the YELAG 2 series, which are interchangeable with bearings in the YEL 2 series, are locked onto the shaft by an eccentric locking collar. The eccentric collar is black oxidized. The bearings are typically used for moderate loads.
- Y-bearings in the YSPAG 2 series, which are interchangeable with bearings in the YSP 2 series, are locked onto the shaft by the patented SKF ConCentra locking technology. This locking technology enables the bearing to accommodate heavier loads than other locking methods.

Other Y-bearings for agricultural applications are available on request:

- bearings with zinc-coated rings
- bearings with a cylindrical outer ring
- bearings with other locking methods

## 2 Y-bearings

### Rubber seating rings

Rubber seating rings in the RIS 2 series (→ **fig. 24**) are primarily intended to “cushion” Y-bearings in stamped steel plummer block housings. Located on the bearing outer ring and in housing bore (→ **fig. 25**), they are intended to dampen vibration and noise and enable the bearings to be displaced slightly in their housings to accommodate minor shaft elongation or misalignment.

The seating rings in the RIS 2 series are made of NBR and have a sphered (convex) outside surface. The rings can withstand temperatures ranging from  $-30$  to  $+100$  °C ( $-20$  to  $+210$  °F). The designations and dimensions for rubber seating rings are listed in **table 4**.

Rubber seating rings are available as an accessory and must be ordered separately. They can be fitted on all SKF Y-bearings, except for Y-bearings with a standard inner ring (17262 and 17263 series). However, Y-bearings in the YET 2 series can be supplied with the seating ring already fitted (→ **fig. 26**). These products are identified by the series prefix **CYS**, followed by the bearing bore diameter and the bearing identification suffix **FM**. E.g. **CYS 20 FM** is a YET 204 bearing with a 20 mm bore, fitted with an RIS 204 rubber seating ring.

# Performance classes

### SKF Energy Efficient (E2) bearings

To meet the ever-increasing demand to reduce friction and energy consumption, SKF has developed the SKF Energy Efficient (E2) performance class of rolling bearings. Y-bearings within this performance class are characterized by a frictional moment in the bearing that is at least 50% lower when compared to a same-sized standard Y-bearing.

This substantial reduction of the frictional moment was achieved by a new contact seal and applying a new, low-friction grease. Due to the reduction of the frictional moment, SKF E2 Y-bearings run up to 30 °C (55 °F) cooler than standard bearings. This extends grease life and potentially bearing service life.

SKF E2 Y-bearings are dimensionally interchangeable with standard bearings enabling both, easy upgrades of existing applications as well as improving the energy efficiency of new applications. Typical applications include conveyors, industrial fans and textile machinery.

SKF E2 Y-bearings are available in the YAR 2, YET 2 and SKF ConCentra YSP 2 series. Bearings in the YET 2 series are supplied with a contact seal on both sides (→ **page 430**). Bearings in the YAR 2 and YSP 2 series are equipped with a contact seal and a plain sheet steel flinger on both sides, improving the sealing effect without increasing friction. The good performance of the seal combined with the cooler running and the extended grease life enable SKF E2 Y-bearings to operate without relubrication under normal operating conditions. When necessary, they can be relubricated through the outer ring (→ *Relubrication*, **page 434**).

## Bearing data

## Temperature limits

The permissible operating temperature for Y-bearings can be limited by:

- the dimensional stability of the bearing rings and balls
- the cage
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing rings and balls

Y-bearings undergo a special heat treatment. The bearing rings and balls are heat stabilized up to at least 150 °C (300 °F).

### Cages

For temperature limits of PA66 cages, refer to *Cage materials* (→ page 152).

### Seals

The permissible operating temperature for NBR seals is -40 to +100 °C (-40 to +210 °F). Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.

### Lubricants

Temperature limits for the greases used in Y-bearings are provided in **table 1** (→ page 431). Temperature limits for other SKF greases are provided under *Lubrication* (→ page 239).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ page 244).

## Permissible speed

Y-bearings should not operate at speeds above the limiting speed listed in the product tables. This speed limit is set by the seals. For Y-bearings with grub screws or an eccentric locking collar, the permissible speed is also influenced by the shaft tolerance. When using these bearings on shafts with wider tolerances than h6, compare the speed values listed in the product tables with those in **table 9**. The lower value is the permissible speed.

The permissible speed of Y-bearings for agricultural applications is valid under the following conditions:

Table 9

<sup>1)</sup> For example: bearing size 06 includes all bearings based on a Y206 bearing, such as YAR 206-2F, YAR 206-101-2F, YAR 206-102-2F, YAR 206-103-2F, YAR 206-104-2F

- outer ring temperature  $\leq 60\text{ }^{\circ}\text{C}$  ( $140\text{ }^{\circ}\text{F}$ )
- environment temperature  $\leq 25\text{ }^{\circ}\text{C}$  ( $80\text{ }^{\circ}\text{F}$ )
- very light to moderate loads ( $P \leq 0,05\text{ C}$ )
- cast iron housing

For other conditions, contact the SKF application engineering service.

For applications operating at elevated speeds or when low vibration levels or quiet running are required, use SKF ConCentra Y-bearings, Y-bearings on an adapter sleeve or Y-bearings with a standard inner ring.

## Design of bearing arrangements

### Axial displacement

Y-bearings are not intended to accommodate axial displacement of the shaft relative to the housing. The distance between bearing positions should therefore be short to avoid excessive induced axial loads as a result of thermal elongation of the shaft.

### Design for small axial displacement

To accommodate small axial displacement, the bearings should be supported by resilient sheet metal support surfaces or walls ( $\rightarrow$  fig. 28).

Fig. 28

## 2 Y-bearings

### Design for larger axial displacement

In applications where there are slow speeds and light loads, a Y-bearing with grub screws can be used to accommodate axial displacement. The shaft at the non-locating bearing position should be provided with one or two grooves 120° apart, to engage a modified grub screw:

- Hexagon socket grub (set) screws with a dog point, in accordance with ISO 4028, but with a fine thread according to **table 10**. The grub screw should be secured by a nut and spring washer or star lock washer (→ **fig. 29**).
- Slotted pan head screws in accordance with ISO 1580, but with fine thread according to **table 10**, locked with a spring or star lock washer (→ **fig. 30**).

The screws and groove(s) accommodate changes in shaft length and prevent the shaft from turning independently of the bearing. The ends of the grub screws should be ground and the sliding surfaces in the shaft grooves coated with a lubricant paste.

## 2 Y-bearings

### Shaft tolerances

Recommended fits for Y-bearings are listed in **table 11**. **Fig. 31** illustrates the relative position of the upper and lower limits of the most commonly used ISO shaft tolerance classes for Y-bearings with grub (set) screws or an eccentric locking collar. The values for these tolerance classes are listed in **table 12**.

For Y-bearings on an adapter sleeve or SKF ConCentra Y-bearings the total radial run-out of the shaft seat should be IT5/2 for tolerance class h9 (E). The values for the ISO tolerance class h9 are listed in **table 12**.

For Y-bearings with a standard inner ring, the same recommendations apply as for standard deep groove ball bearings (→ **table 11**). The values for these ISO tolerance classes are listed in **table 7** (→ **page 178**).

<sup>1)</sup> All ISO tolerance classes are valid with the envelope requirement (such as h7(E)) in accordance with ISO 14405-1.

## Mounting and dismounting

When mounting Y-bearings on a shaft, suitable tools should be used and the locking components should be tightened to the torque values / tightening angles listed in **tables 13 to 15** (→ **pages 452 to 454**).

For SKF ConCentra Y-bearings, mounting kits are available from SKF (designation 626830), which include mounting instructions, hexagonal keys and torque indicators. The correct tightening torque is achieved when the long end of the hexagonal key comes in contact with the torque indicator (→ **fig. 32**).

For additional information about mounting and dismounting Y-bearings and assembling Y-bearing units, refer to the *SKF bearing maintenance handbook*.

Grub screws in SKF ConCentra Y-bearings – key sizes and recommended tightening torques

Bearing size <sup>1)</sup>		Screw size	Hexagonal key size N	Tightening torque
from	to			
–	–	–	mm	Nm
05	06	M5	2,5	4,2
07	13	M6	3	7,4

<sup>1)</sup> For example: bearing size 07 includes all bearings based on a Y 207 bearings such as YSP 207 SB-2F, YSP 207-104 SB-2F, YSP 207-106 SB-2F, YSP 207-107 SB-2F

### Assembling Y-bearings into housings with fitting slots

When installing a Y-bearing into a housing with fitting slots, the bearing should be inserted into the fitting slot in the housing bore (→ fig. 33) and then swivelled into position.

When installing Y-bearings with two lubrication holes in the outer ring and the bearing has to be relubricated, make sure that one of the relubrication holes in the bearing coincides with the relubrication facility in the housing (→ fig 34, right). Be sure that the other relubrication hole is not aligned with either of the fitting slots, otherwise grease leakage may result (→ fig. 34, left).

Fig. 33

Fig. 34

Eccentric locking collars should be removed from the bearing prior to installation and reinstalled when the bearing is in position in the housing.

SKF recommends installing SKF Y-bearings only into SKF Y-housings to avoid a mismatch of components and to enable proper bearing relubrication.

### SKF ConCentra Y-bearings

When mounting SKF ConCentra Y-bearings, position the collar so that one grub screw is directly opposite the slit in the sleeve.

**CAUTION:** Do not tighten the grub (set) screws until the bearing is positioned on the shaft. If the screws are tightened prematurely, the stepped sleeve may deform. No attempt should be made to disassemble the sleeve and the mounting collar from the bearing prior to installation.

To dismount SKF ConCentra Y-bearings loosen the grub screws first. Then gently tap the edge of the sleeve on the collar side, or the inner ring side face on the opposite side to loosen the lock (→ **fig. 35**).

# Designation system

**Prefixes**

**E2.** SKF Energy Efficient bearing

**Basic designation**

**Bearing design**

- YAR** Bearing with grub screws, inner ring extended on both sides
- YARAG** Bearing with grub screws, inner ring extended on both sides, for agricultural applications
- YAT** Bearing with grub screws, inner ring extended on one side
- YEL** Bearing with an eccentric locking collar, inner ring extended on both sides
- YELAG** Bearing with an eccentric locking collar, inner ring extended on both sides, for agricultural applications
- YET** Bearing with an eccentric locking collar, inner ring extended on one side
- YSA** Bearing with a tapered bore, inner ring symmetrically extended on both sides
- YSP** Bearing with SKF ConCentra locking technology, inner ring symmetrically extended on both sides
- YSPAG** Bearing with SKF ConCentra locking technology, inner ring symmetrically extended on both sides, for agricultural applications
- 172** Bearing with a standard inner ring

**Dimension series**

- 2** Outside diameter to ISO 15, diameter series 2
- 62** Bearing in accordance with ISO 15, dimension series 02, sphered outside surface
- 63** Bearing in accordance with ISO 15, dimension series 03, sphered outside surface

**Bore diameter d**

**Bearings for metric shafts**

- 03/12** d = 12 mm
- 03/15** d = 15 mm
- 03** d = 17 mm
- 04** d = 20 mm
- to
- 20** d = 100 mm

**Bearings for inch shafts**

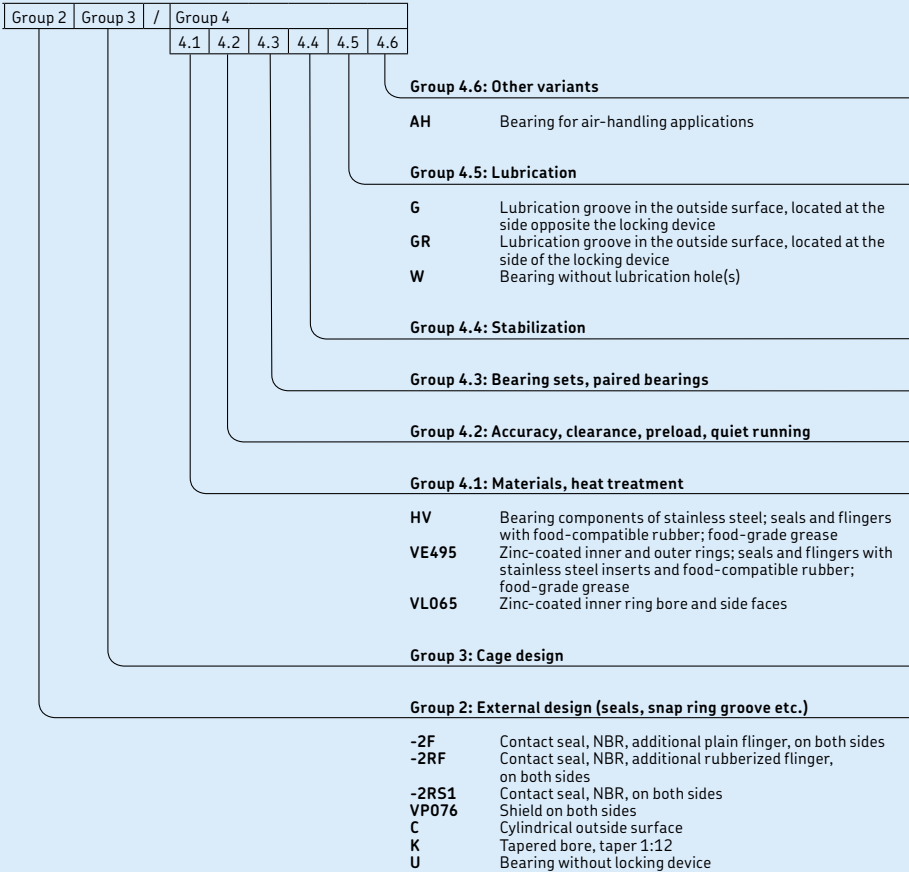

- Three-digits combination that follows the designation of the basic metric bearing and is separated from this by a hyphen; the first digit is the number of whole inches and the second and third digits are the number of sixteenths of an inch, e.g. 204-012
- 008** d = 1/2 in. (12,7 mm)
  - to
  - 300** d = 3 in. (76,2 mm)

**Suffixes**

**Group 1: Internal design**

**SB** SKF ConCentra ball bearing with shortened inner ring

## Designs and variants

Angular contact ball bearings have raceways in the inner and outer rings that are displaced with respect to each other in the direction of the bearing axis. This means that they are designed to accommodate combined loads, i.e. simultaneously acting radial and axial loads.

The axial load carrying capacity of angular contact ball bearings increases with increasing contact angle. The contact angle is defined as the angle between the line joining the points of contact of the ball and the raceways in the radial plane, along which the load is transmitted from one raceway to another, and a line perpendicular to the bearing axis (→ fig. 1).

SKF angular contact ball bearings are manufactured in a wide variety of designs and sizes. The most commonly used designs are:

- single row angular contact ball bearings
- double row angular contact ball bearings
- four-point contact ball bearings

Angular contact ball bearings listed in this catalogue constitute the basic SKF assortment and are only part of the total assortment. Other SKF angular contact ball bearings include:

- Super-precision angular contact ball bearings  
For additional information, refer to the product information available online at [skf.com/super-precision](http://skf.com/super-precision).
- Thin section angular contact ball bearings  
For additional information, contact the SKF application engineering service.
- Hub bearing units  
Information about these products can be supplied on request.

Angular contact ball bearings with a larger size than those listed in the product tables are available on request. For information about these bearings, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings), or contact the SKF application engineering service.

### Single row angular contact ball bearings

SKF single row angular contact ball bearings (→ fig. 2) can accommodate axial loads in one direction only. A single row bearing is typically adjusted against a second bearing.

The bearings are non-separable and the bearing rings have one high and one low shoulder. The low shoulder enables a large number of balls to be incorporated in the bearing, giving it a relatively high load carrying capacity.

The standard assortment of SKF single row angular contact ball bearings comprises bearings in the 72 B(E) and 73 B(E) series. Some sizes in the 70 B series are also available.

**Matrix 1** (→ **page 500**) provides an overview of the standard assortment. In addition, SKF single row angular contact ball bearings are available in many other designs, dimension series, and sizes. For additional information, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings).

### Basic design bearings

Basic design bearings are intended for arrangements where only one bearing is used at each bearing position. They have Normal tolerances concerning bearing width and stand-out of the rings. Therefore, they are not suitable for mounting immediately adjacent to each other.

### Bearings for universal matching

Bearings for universal matching are intended to be used in sets. The width and the stand-out of the rings are manufactured to close tolerances. When two bearings are mounted immediately adjacent to each other, a given internal clearance or preload or an even load distribution between the two bearings is obtained without the use of shims or similar devices.

Bearings for universal matching can also be beneficial in arrangements with single bearings. Most bearings belong to the SKF Explorer performance class and as such have higher precision, increased load carrying capacity and speed capability.

Bearings for universal matching in the 72 B(E) and 73 B(E) series are identified by the suffix CA, CB or CC for internal clearance or GA, GB or GC for preload. Bearings for universal matching in the 70 B series are identified by the suffix G for clearance. When ordering, indicate the number of individual bearings required and not the number of sets.

Fig. 2

### 3 Angular contact ball bearings

#### Paired mounting

Paired mounting can be done in three ways (→ fig. 3):

- **Tandem arrangement**  
A tandem arrangement is used when the load carrying capacity of a single bearing is inadequate. When arranged in tandem, the load lines are parallel and the radial and axial loads are equally shared by the bearings. However, the bearing set can accommodate axial loads in one direction only. If axial loads act in both directions, a third bearing, adjusted against the tandem pair, must be added.
- **Back-to-back arrangement**  
Mounting two bearings back-to-back provides a relatively stiff bearing arrangement, which can also accommodate tilting moments. When arranged back-to-back, the load lines diverge toward the bearing axis. Axial loads in both directions can be accommodated, but only by one bearing in each direction.
- **Face-to-face arrangement**  
Mounting two bearings face-to-face is not as stiff as a back-to-back arrangement, but less sensitive to misalignment. When arranged face-to-face, the load lines converge toward the bearing axis. Axial loads in both directions can be accommodated, but only by one bearing in each direction.

#### Double row angular contact ball bearings

SKF double row angular contact ball bearings (→ fig. 4) correspond in design to two single row angular contact ball bearings arranged back-to-back, but take up less axial space. They can accommodate radial loads as well as axial loads in both directions. They provide stiff bearing arrangements and are able to accommodate tilting moments.

The standard assortment of SKF double row angular contact ball bearings comprises bearings in the 32 A, 33 A and 33 D series. **Matrix 2 (→ page 501)** provides an overview of the standard assortment. For information about other double row angular contact ball bearings, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings).

Bearings in the 52 and 53 series, in accordance with ABMA standards, are no longer available from SKF and have been replaced with 32 and 33 series bearings in accordance with ISO. With the exception of size 3200, 32 and 33 series bearings are dimensionally interchangeable with bearings in the 52 and 53 series. Size 3200 has a width of 14 mm instead of 14,3 mm.

Fig. 3

**Basic design bearings**

Basic design bearings (designation suffix A) have an optimized internal geometry to provide high radial and axial load carrying capacity and quiet operation. Basic design bearings that are also available capped may have recesses in the inner and outer rings (→ **fig. 5**).

**Bearings with a two-piece inner ring**

Bearings with a two-piece inner ring (→ **fig. 6**) incorporate a large number of large balls, giving the bearing its high load carrying capacity, especially in the axial direction.

Bearings in the 33 D series are separable, i.e. the outer ring with ball and cage assemblies can be mounted independently of the inner ring halves.

Bearings in the 33 DNRCBM series are non-separable. They have a snap ring groove with a snap ring in the outer ring, enabling simple and space-saving axial location in the housing. Bearings in the 33 DNRCBM series have been designed specifically for centrifugal pumps, but can also be used in other applications.

### 3 Angular contact ball bearings

#### Four-point contact ball bearings

Four-point contact ball bearings (→ **fig. 7**) are radial single row angular contact ball bearings with raceways that are designed to support axial loads in both directions. For a given axial load, a limited radial load can be supported (→ *Load ratio*, **page 499**). These bearings take up considerably less axial space than double row bearings.

The inner ring is split. This enables a large number of balls to be incorporated in the bearing, giving the bearing its high load carrying capacity. The bearings are separable, i.e. the outer ring with ball and cage assembly can be mounted separately from the two inner ring halves.

Both inner ring halves of SKF Explorer four-point contact ball bearings have a recessed shoulder. This improves oil flow when the bearing is used together with an SKF cylindrical roller bearing (→ **fig. 12**, **page 499**). In addition, these recesses can be used to facilitate dismounting.

The standard assortment of SKF four-point contact ball bearings comprises bearings in the QJ 2 and QJ 3 series. **Matrix 3** (→ **page 502**) provides an overview of the standard assortment. For information about other four-point contact ball bearings, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings).

### Cages

Depending on their design, series and size, SKF angular contact ball bearings are fitted with one of the cages shown in **table 1**. Double row bearings are equipped with two cages. The stamped steel cage in double row bearings is not identified in the bearing designation. For information about the availability of cages for the various bearing designs, series and sizes, refer to **matrices 1 to 3** (→ **pages 500 to 502**).

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

#### Sealing solutions

SKF supplies the most common basic design double row angular contact ball bearings capped with a contact seal or shield on both sides (→ **matrix 2, page 501**). For additional information about the suitability of seals or shields under various conditions, refer to *Sealing solutions* (→ **page 226**).

Bearings capped on both sides are lubricated for the life of the bearing and should not be washed or relubricated. The bearings are considered maintenance-free. If they are to be hot mounted, an induction heater should be used. SKF does not recommend heating capped bearings above 80 °C (175 °F). However, if higher temperatures are necessary make sure that the temperature does not exceed the permissible temperature of either the seal or grease, whichever is lowest. During start-up, grease may leak at the inner ring. For bearing arrangements where this would be detrimental, special design steps must be undertaken. For additional information, contact the SKF application engineering service.

#### Shields

Shields are made of sheet steel. SKF supplies shields in two designs. The shields used in smaller bearings have an extension in the shield bore to form a long, narrow gap with the land of the inner ring shoulder (→ **fig. 8a**). The shields used in larger bearings and in all SKF Explorer bearings extend into a recess on the inner ring (→ **fig. 8b**).

SKF double row angular contact ball bearings with a shield on both sides are identified by the designation suffix 2Z.

#### Contact seals

Contact seals (→ **fig. 9**) are made of NBR and are reinforced with a sheet steel insert. These seals, which are fitted in a recess on the outer ring, make good, positive contact with the recess. The seal lip exerts light pressure against the recess on the inner ring to provide an effective seal.

SKF double row angular contact ball bearings with a contact seal on both sides are identified by the designation suffix 2RS1.

### Greases for capped bearings

Capped double row angular contact ball bearings are filled with one of the following greases (→ table 2):

- The standard grease is GJN.
- In Europe, MT33 is commonly used and widely available.
- SKF Energy Efficient angular contact ball bearings are filled with the low-friction grease GE2.
- Other greases listed in **table 2** can be supplied on request.

The standard grease is not identified in the bearing designation (no designation suffix). Other greases are indicated by the corresponding grease suffix.

#### Locating slots

SKF four-point contact ball bearings can be supplied with two locating slots in the outer ring (→ **fig. 10**) to prevent it from turning (designation suffix N2). The locating slots are positioned 180° apart. The dimensions and tolerances of the locating slots are in accordance with ISO 20515 and are listed in **table 3**. Some SKF single row angular contact ball bearings can be supplied with one locating slot in the outer ring (designation suffix N1).

## Performance classes

### SKF Explorer bearings

In response to the ever-demanding performance requirements of modern machinery, SKF developed the SKF Explorer performance class of rolling bearings.

SKF Explorer angular contact ball bearings realized this substantial improvement in performance by optimizing the internal geometry and surface finish of all contact surfaces, redesigning the cage, combining the extremely clean and homogenous steel with a unique heat treatment and improving the quality and consistency of the balls.

These improvements provide the following benefits:

- higher dynamic load carrying capacity
- less sensitivity to heavy axial loads
- improved wear-resistance
- reduced noise and vibration levels
- less frictional heat
- significantly extended bearing service life

These bearings reduce environmental impact by enabling downsizing and reducing both lubricant and energy consumption. Just as importantly, SKF Explorer bearings can reduce the need for maintenance and contribute to increased productivity.

SKF Explorer bearings are shown with an asterisk in the product tables. The bearings retain the designation of earlier standard bearings. However, each bearing and its box are marked with the name "SKF Explorer".

### SKF Energy Efficient (E2) bearings

To meet the ever-increasing demand to reduce friction and energy consumption, SKF has developed the SKF Energy Efficient (E2) performance class of rolling bearings. SKF E2 angular contact ball bearings are characterized by a frictional moment in the bearing that is at least 30% lower when compared to a same-sized standard SKF bearing. Due to the reduction of the frictional moment, SKF E2 double row angular contact ball bearings run up to 20 °C (35 °F) cooler than standard bearings. This extends grease life and potentially bearing service life.

The bearings realized the substantial reduction of the frictional moment by optimizing the internal geometry of the bearing and applying a new, low-friction grease.

SKF E2 double row angular contact ball bearings are available in the 32 and 33 dimension series (→ **matrix 2, page 501**). The bearings are equipped with a shield on both sides and lubricated for the life of the bearing.

### Load carrying capacity of bearing pairs

The values for basic load ratings and fatigue load limits listed in the product tables apply to single bearings. For bearing pairs mounted immediately adjacent to each other the following values apply:

- basic dynamic load rating for standard bearings in all arrangements and for SKF Explorer bearings in a back-to-back or face-to-face arrangement  
 $C = 1,62 C_{\text{single bearing}}$
- basic dynamic load rating for SKF Explorer bearings in a tandem arrangement  
 $C = 2 C_{\text{single bearing}}$
- basic static load rating  
 $C_0 = 2 C_{0 \text{ single bearing}}$
- fatigue load limit  
 $P_u = 2 P_{u \text{ single bearing}}$

### Calculating the axial load for bearings mounted singly or paired in tandem

When a radial load is applied to a single row angular contact ball bearing, the load is transmitted from one raceway to the other at an angle to the bearing axis and an internal axial load is induced. This must be considered when calculating the equivalent bearing loads for bearing arrangements consisting of two single bearings and/or bearing pairs arranged in tandem.

The necessary equations are provided in **table 11** (→ **page 496**), for the various bearing arrangements and load cases. The equations are only valid if the bearings are adjusted against each other to practically zero clearance, but without any preload. In the arrangements shown, bearing A is subjected to a radial load  $F_{rA}$  and bearing B to a radial load  $F_{rB}$ . Both  $F_{rA}$  and  $F_{rB}$  are always considered positive, even when they act in the direction opposite to what is shown in the figures. The radial loads act at the pressure centres of the bearings (→ distance  $a$  in the product tables).

The variable  $R$  from **table 11** (→ **page 496**) takes into account the contact conditions inside the bearing. The values for  $R$  can be obtained from **diagram 1**, as a function of the ratio  $K_a/C$ .  $K_a$  is the external axial force acting

on the shaft or on the housing and  $C$  is the basic dynamic load rating of the bearing, which must accommodate the external axial force.

Use  $R = 1$  for  $K_a = 0$ .

## Temperature limits

The permissible operating temperature for angular contact ball bearings can be limited by:

- the dimensional stability of the bearing rings and balls
- the cage
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing rings and balls

SKF angular contact ball bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 150 °C (300 °F).

### Cages

Steel, brass or PEEK cages can be used at the same operating temperatures as the bearing rings and balls. For temperature limits of cages made of other polymer materials, refer to *Cage materials* (→ **page 152**).

### Seals

The permissible operating temperature for NBR seals is -40 to +100 °C (-40 to +210 °F). Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.

### Lubricants

Temperature limits for greases used in capped SKF angular contact ball bearings are provided in **table 2** (→ **page 483**). Temperature limits for other SKF greases are provided under *Lubrication* (→ **page 239**).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

## Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**). If no reference speed is listed in the product tables, the limiting speed is the permissible speed.

### Bearing pairs

For bearings arranged in pairs, the permissible speed calculated for a single bearing should be reduced to approximately 80% of the quoted value.

### Single row angular contact ball bearings

#### Proper adjustment

Single row angular contact ball bearings must either be used with a second bearing or in sets (→ **fig. 11**). The bearings must be adjusted against each other until the requisite clearance or preload is obtained (→ *Bearing preload*, **page 214**).

When universally matchable bearings are mounted immediately adjacent to each other, there is no need for adjustment. The requisite clearance or preload is obtained by choosing bearings from an appropriate clearance or preload class and by applying suitable fits for the bearings on the shaft and in the housing.

The performance and operational reliability of single bearings depend on proper adjustment while universally matchable bearings depend on the correct selection of clearance or preload. If there is too much clearance in the bearing arrangement during operation, the load carrying capacity of the bearings is not fully utilized. Excessive preload produces more

friction and higher operating temperatures, leading to a reduction in bearing service life.

#### Axial loads in one direction

Back-to-back and face-to-face arrangements require special attention when the axial load acts predominantly in one direction. This creates unfavourable rolling conditions for the balls of the axially unloaded bearing and can lead to increased noise levels, discontinuity in the lubricant film and increased stresses on the cage. When the axial load acts predominantly in one direction, SKF recommends zero operating clearance, which can be attained by using springs.

#### Load ratio

Because of the 40° contact angle, favourable rolling conditions for bearings in the 70 B, 72 B(E) and 73 B(E) series require a load ratio of  $F_a/F_r \geq 1$ . A load ratio of  $F_a/F_r < 1$  can reduce bearing service life.

Fig. 11

## Four-point contact ball bearings

### Used as a thrust bearing

Four-point contact ball bearings are often used as pure thrust bearings, together with a radial bearing (→ **fig. 12**). When used in this way, the bearing should be mounted with radial clearance in the housing.

When a four-point contact ball bearing is used together with a cylindrical roller bearing, the radial internal clearance of the cylindrical roller bearing should be smaller than the theoretical radial internal clearance of the four-point contact ball bearing after both have been mounted. The theoretical radial clearance can be calculated from

$$C_r = 0,7 C_a$$

where

$C_r$  = theoretical radial internal clearance

$C_a$  = axial internal clearance (→ **table 8, page 490**)

The outer ring of the four-point contact ball bearing must be able to accommodate thermal movements. Therefore, it should not be clamped axially, but a small gap should be maintained between the outer ring and the cover flange. To prevent the outer ring from turning, bearings with locating slots should be used (→ **fig. 12**). If clamping the outer ring cannot be avoided, the outer ring must be carefully centred during mounting.

### Vertical shafts

When four-point contact ball bearings with a machined brass cage (designation suffix MA) are used on a vertical shaft, the limiting speed listed in the product tables should be reduced to 70% of the value listed in the product tables. As with all vertical shafts, be sure that the bearings are adequately lubricated.

### Load ratio

Four-point contact ball bearings do not function properly unless the balls contact only one inner ring raceway and the opposite side of the outer ring raceway. This is the case when the load ratio  $F_a/F_r \geq 1,27$ . A load ratio of  $F_a/F_r < 1,27$  can reduce bearing service life.

## 4 Self-aligning ball bearings

### Designs and variants

Self-aligning ball bearings have two rows of balls and a common sphered raceway in the outer ring. The bearings are insensitive to angular misalignment of the shaft relative to the housing. Self-aligning ball bearings generate less friction than any other type of rolling bearing, which enables them to run cooler even at high speeds.

SKF self-aligning ball bearings are available in several designs, including:

- basic design bearings (→ **fig. 1**)
- bearings with an extended inner ring (→ **fig. 2**)
- sealed bearings (→ **fig. 3**)

### Basic design bearings

Basic design self-aligning ball bearings are available with a cylindrical bore and, for certain sizes, with a 1:12 tapered bore (designation suffix K).

Large self-aligning ball bearings in the 130 and 139 series, originally developed for specific applications in the paper industry, can be used in any application where low friction is preferred over high load carrying capacity. These bearings are equipped with an annular groove and three equally spaced lubrication holes in the outer ring and six equally spaced lubrication holes in the inner ring (→ **fig. 4**).

The balls of some bearings in the 12 and 13 series protrude from the side faces of the bearing. The values of the protrusion are listed in **table 1** and should be considered when designing components in close proximity to the bearing.

## 4 Self-aligning ball bearings

### Bearings with an extended inner ring

Self-aligning ball bearings with an extended inner ring are designed for less demanding applications that use commercial grade shafting. The special bore tolerance, class JS7 (→ **table 4, page 543**), facilitates mounting and dismounting.

Self-aligning ball bearings with an extended inner ring are located axially on the shaft by means of a slot at one end of the inner ring that engages a pin or shoulder screw (→ **fig. 5**) fitted to the shaft. The holding device also prevents the shaft from spinning in the bearing bore.

When two of these bearings are used to support a shaft, they should be positioned so that the inner ring slots either face each other, or are opposed to each other (→ **fig. 5**). If this is not the case, the shaft is located axially in one direction only.

### Cages

Depending on their series and size, SKF self-aligning ball bearings are fitted with one of the cages shown in **table 2**.

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the

suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

### Sealing solutions

Some self-aligning ball bearings in the 22 and 23 series are also available with seals (→ **fig. 6**).

Sealed bearings have a contact seal on both sides that is made of oil and wear-resistant NBR and reinforced with a sheet steel insert (designation suffix 2RS1).

Sealed bearings are lubricated for the life of the bearing and should not be washed or relubricated. The bearings are considered maintenance-free. If they are to be hot mounted, SKF does not recommend heating the bearings above 80 °C (175 °F).

### Greases for sealed bearings

Depending on their outside diameter, sealed bearings are filled with one of the two greases listed in **table 3**. Both have good corrosion inhibiting properties.

## Temperature limits

The permissible operating temperature for self-aligning ball bearings can be limited by:

- the dimensional stability of the bearing rings and balls
- the cage
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing rings and balls

SKF self-aligning ball bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 120 °C (250 °F).

### Cages

Steel or brass cages can be used at the same operating temperatures as the bearing rings and balls. For temperature limits of polymer cages, refer to *Cage materials* (→ **page 152**).

### Seals

The permissible operating temperature for NBR seals is -40 to +100 °C (-40 to +210 °F). Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.

### Lubricants

Temperature limits for the greases used in sealed SKF self-aligning ball bearings are provided in **table 3** (→ **page 541**). Temperature limits for other SKF greases are provided under *Lubrication* (→ **page 239**).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

## Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**). If no reference speed is listed in the product tables, the limiting speed is the permissible speed.

## 4 Self-aligning ball bearings

### Design of bearing arrangements

#### Bearings on sleeves

Self-aligning ball bearings with a tapered bore can be mounted on plain or stepped shafts with an adapter sleeve (→ **fig. 7**) or on stepped shafts with a withdrawal sleeve (→ **fig. 8**). Adapter sleeves are supplied complete with a locking device. For additional information about sleeves, refer to *Bearing accessories* (→ **page 1269**).

Adapter sleeves are more popular than withdrawal sleeves as they do not require axial locating devices on the shaft. Therefore, only

adapter sleeves are listed together with the suitable bearings in this catalogue.

When using sealed self-aligning ball bearings on an adapter sleeve, the locking device must not interfere with the seal. To avoid this, use an appropriate SKF adapter sleeve assembly, as listed in the product tables (→ **page 564**). Sealed bearings use either a standard sleeve or an E design sleeve (→ **fig. 9**). Alternatively, a spacer ring can be inserted between the bearing and the lock washer.

### Bearing / adapter sleeve kits

To facilitate procurement and to provide the correct bearing / sleeve combination, SKF offers kits for the most popular sizes, containing the self-aligning ball bearing together with the suitable adapter sleeve assembly.

These kits are listed in **table 7**. The technical data for bearings and sleeves are listed in the relevant product tables.

### Appropriate bearing housings

The combination of an SKF self-aligning ball bearing, adapter sleeve, where needed, and an appropriate SKF bearing housing provides a cost-effective, interchangeable and reliable solution that fulfils the demand for easy maintenance. Appropriate SKF housings are available in a variety of designs and sizes for a wide range of applications. The designs include:

- SNL, SE plummer (pillow) block housings in the 2, 3, 5 and 6 series
- FNL flanged housings
- SAF plummer (pillow) block housings for inch shafts

Additional information about SKF bearing housings is available online at [skf.com/housings](http://skf.com/housings).

## 4 Self-aligning ball bearings

### Mounting bearings with a tapered bore

Bearings with a tapered bore are always mounted with an interference fit. To obtain the proper degree of interference, one of the following methods can be used:

- 1 feeling the clearance reduction by swivelling the outer ring
- 2 measuring the lock nut tightening angle
- 3 measuring the axial drive-up
- 4 applying the SKF Drive-up Method

For additional information about these mounting methods, refer to *Mounting, dismounting and bearing care* (→ **page 271**), or the *SKF bearing maintenance handbook*.

The most suitable method for bearings mounted on shafts with a diameter  $\geq 50$  mm is the SKF Drive-up Method, which is a fast, reliable and safe method to achieve the appropriate interference fit. Additional information is available online at [skf.com/drive-up](http://skf.com/drive-up).

Recommended values to apply methods 2 and 3 are listed in **table 8**.

#### Feeling the clearance reduction by swivelling the outer ring

When mounting self-aligning ball bearings with Normal radial clearance, it is generally sufficient to check clearance reduction during axial drive-up by turning and swivelling the outer ring (→ **fig. 10**). The clearance reduction in the bearing is sufficient when the outer ring can be turned easily, but a slight resistance is felt when it is swivelled out.

## Designs and variants

SKF cylindrical roller bearings are available in many designs, series and sizes. The majority are single row bearings with a cage. High-capacity bearings, single and double row full complement bearings (without a cage) complete the SKF standard assortment listed in this catalogue.

Bearings with a cage can accommodate heavy radial loads, rapid accelerations and high speeds. Full complement bearings incorporate a maximum number of rollers and are therefore suitable for very heavy radial loads at moderate speeds. SKF high-capacity cylindrical roller bearings combine the high load carrying capacity of a full complement bearing with the high speed capability of a bearing with a cage.

The factors that influence SKF cylindrical roller bearing performance and service life include but are not limited to the following:

- Roller end / flange contact area**  
 SKF cylindrical roller bearings have two integral flanges on either the inner or outer ring to guide the rollers. The bearings have “open” flanges, i.e. the inward face of the flange is inclined by a defined angle (→ **fig. 1**). The flange design, together with the roller end design and surface finish, promote the formation of a lubricant film to reduce friction and frictional heat.

- Logarithmic roller profile**  
 The roller profile determines the stress distribution in the roller/raceway contact area. As a result, the rollers in SKF cylindrical roller bearings have a logarithmic profile to distribute loads evenly along the rollers. This prevents stress peaks at the roller ends to extend bearing service life (→ **fig. 2**). The logarithmic profile also reduces sensitivity to misalignment and shaft deflection.

- Surface finish**  
 The surface finish on the contact surfaces of the rollers and raceways maximizes the formation of a hydrodynamic lubricant film and optimizes the rolling motion of the rollers. The benefits derived from this, compared with traditional designs, include enhanced operational reliability.

- Interchangeable components**  
 The separable components of same-sized SKF cylindrical roller bearings are interchangeable (→ **fig. 3**). Any bearing ring with a roller and cage assembly can be assembled with any removable ring of the same bearing type and size having the same internal clearance class. This is particularly important when bearings and their components must be mounted independently of each other.

In addition to the bearings listed in this catalogue the comprehensive SKF assortment of cylindrical roller bearings includes:

- super-precision all-steel or hybrid cylindrical roller bearings
- cylindrical roller bearings and bearing units for railway axleboxes
- cylindrical roller bearings for traction motors for railway applications
- multi-row cylindrical roller bearings for rolling mills
- backing bearings for cluster mills
- indexing roller units for continuous furnaces

## 5 Cylindrical roller bearings

### Single row cylindrical roller bearings

Single row cylindrical roller bearings are separable, i.e. the bearing ring with the roller and cage assembly can be separated from the other ring. This simplifies mounting and dismounting, particularly when load conditions require both rings to have an interference fit.

#### Basic design bearings

SKF basic design single row cylindrical roller bearings are available in several designs. The main difference is the configuration of the flanges. The most popular designs (→ **fig. 4**) are listed in this catalogue and include:

- NU design  
NU design bearings have two integral flanges on the outer ring and no flanges on the inner ring. These bearings can accommodate axial displacement of the shaft relative to the housing in both directions.
- N design  
N design bearings have two integral flanges on the inner ring and no flanges on the outer ring. These bearings can accommodate axial displacement of the shaft relative to the housing in both directions.
- NJ design  
NJ design bearings have two integral flanges on the outer ring and one on the inner ring. These bearings are used to locate the shaft axially in one direction. They can accommodate axial displacement of the shaft relative to the housing in one direction only.

- NUP design  
NUP design bearings have two integral flanges on the outer ring and one integral flange and one non-integral flange i.e. a loose flange ring, on the inner ring. These bearings are used to locate the shaft axially in both directions.

### Angle rings (thrust collars)

To stabilize NU and NJ design bearings in the axial direction, SKF can supply angle rings (→ **fig. 5**). When used with an angle ring, NU design bearings locate the shaft axially in one direction. Angle rings should not be used on both sides of NU design bearings as this can lead to axial compression of the rollers. NJ design bearings combined with an angle ring are used to locate the shaft axially in both directions.

There can be several reasons to design angle rings into a bearing arrangement:

- When NJ or NUP design locating bearings are not in the product range.
- To provide a more effective inner ring seat for heavily loaded bearings in the locating position. An arrangement of an NJ design bearing with an HJ angle ring have a full width inner ring seat, instead of using an NUP design bearing that has a shorter inner ring and a loose flange.
- To simplify design or mounting procedures.

SKF angle rings are made of carbon chromium steel. They are hardened and ground. The maximum axial run-out is in accordance with the Normal tolerance class for the appropriate bearing. Available angle rings are listed in the product tables. They are identified by the series designation HJ followed by the appropriate bearing dimension series and size. Angle rings must be ordered separately.

### Other variants

#### Bearings without an inner or outer ring

SKF can supply NU design cylindrical roller bearings without an inner ring (RNU series, → **fig. 6**) and N design bearings without an outer ring (RN series, → **fig. 6**). These bearings are typically used in applications where hardened and ground raceways are provided on the shaft or in the housing (→ *Raceways on shafts and in housings*, **page 210**). Because RNU bearings do not have an inner ring, the shaft diameter can be larger to provide a stronger, stiffer shaft arrangement. Additionally, the possible axial displacement of the shaft relative to the housing is limited only by the width of the raceway on the shaft for RNU bearings, or in the housing for RN bearings.

**Bearings with a tapered bore**

Some single row cylindrical roller bearings can be supplied with a 1:12 tapered bore (designation suffix K, → **fig. 7**). Bearings with a tapered bore have radial internal clearance greater than corresponding bearings with a cylindrical bore. For additional information, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings) or contact the SKF application engineering service. Check availability prior to ordering.

**Bearings with a snap ring groove**

Single row cylindrical roller bearings can be supplied with a snap ring groove in the outer ring (designation suffix N, → **fig. 8**). These bearings can be axially located in the housing by a snap ring to save space and reduce installation time. The dimensions of the snap rings and snap ring grooves are in accordance with ISO 464. Check availability prior to ordering.

**Bearings with locating slots**

When the outer ring must be mounted with a loose fit, bearings with locating slots can be used to prevent the outer ring from turning. Single row cylindrical roller bearings can be supplied with one or two locating slots (designation suffix N1 or N2) in the outer ring (→ **fig. 9**). The two locating slots are positioned 180° apart. The dimensions of the locating slots are in accordance with ISO 20515. Check availability prior to ordering.

### Other designs

SKF single row cylindrical roller bearings can have the extended inner ring or flange configurations shown in **fig. 10**. For additional information about these bearings and customized designs, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings) or contact the SKF application engineering service.

### High-capacity cylindrical roller bearings

SKF high-capacity cylindrical roller bearings (→ **fig. 11**) have the high load carrying capacity of full complement bearings and the high speed capability of bearings with a cage. They are designed for applications such as industrial gearboxes, gearboxes in wind turbines and mining equipment.

The superior performance of SKF high-capacity cylindrical roller bearings is mainly a result of the cage design. The window-type metal cage is designed so that its cage bars are displaced relative to the roller pitch diameter. This enables the rollers to be placed closer to each other, creating room for additional rollers (→ **fig. 12**). Depending on the bearing series, the cage can be either inner or outer ring centred. These cages are beneficial if high speeds, rapid accelerations or shock loads occur.

The rings and rollers in SKF high-capacity cylindrical roller bearings are coated with black oxide (designation suffix L4B) to minimize the risk of smearing or wear, especially during the running-in period.

## 5 Cylindrical roller bearings

### Bearings with an inner ring centred cage

SKF high-capacity cylindrical roller bearings with an inner ring centred cage (→ **fig. 13**) are identified by the series designation NCF .. ECJB (→ **product tables**). They are used to locate the shaft axially in one direction and eventually to accommodate axial displacement of the shaft relative to the housing in the opposite direction.

When the outer raceway is integrated into the application, these bearings can be supplied without an outer ring (RN .. ECJB series).

### Bearings with an outer ring centred cage

SKF high-capacity cylindrical roller bearings with an outer ring centred cage (→ **fig. 14**) are identified by the series designation NJF .. ECJA. For some sizes, the bearings contain more rollers than same-sized bearings with an inner ring centred cage. They are used to locate the shaft axially in one direction and eventually to accommodate axial displacement of the shaft relative to the housing in the opposite direction. For additional information, contact the SKF application engineering service.

When the inner raceway is integrated into the application, these bearings can be supplied without an inner ring (RNU .. ECJA series).

### Separable bearings with an inner ring centred cage

SKF separable high-capacity cylindrical roller bearings with an inner ring centred cage (→ **fig. 15**) are identified by the series designation NUH .. ECMH (→ **product tables**). The bearing outer ring with the roller and cage assembly can be separated from the inner ring. This simplifies mounting and dismounting, particularly when load conditions require both rings to have an interference fit. These bearings can accommodate axial displacement of the shaft relative to the housing in both directions.

### Double row bearings

Double row SKF high-capacity cylindrical roller bearings with cages can be supplied on request. They are based on the design of double row full complement bearings (→ **page 579**, e.g. NNCF design). For additional information, contact the SKF application engineering service.

NUH .. ECMH

## 5 Cylindrical roller bearings

### Single row full complement cylindrical roller bearings

The basic SKF assortment of single row full complement cylindrical roller bearings listed in this catalogue includes NCF and NJG design bearings (→ **fig. 16**). They are used to locate the shaft axially in one direction and eventually to accommodate axial displacement of the shaft relative to the housing in the opposite direction.

#### NCF design

NCF design bearings have two integral flanges on the inner ring and one on the outer ring. A retaining ring inserted in the outer ring on the side opposite the integral flange holds the bearing together. The retaining ring should not be loaded axially during operation.

#### NJG design

NJG design bearings, which comprise the heavy 23 dimension series, are intended for very heavily loaded, slow-speed applications. These bearings have two integral flanges on the outer ring and one on the inner ring. NJG design bearings have a self-retaining roller complement. Therefore, the outer ring with its two integral flanges together with the roller complement can be separated from the inner ring without having to take special precautions to prevent the rollers from falling out. This simplifies mounting and dismounting.

Fig. 16

## Double row full complement cylindrical roller bearings

The basic SKF assortment of double row full complement cylindrical roller bearings listed in this catalogue includes NNCL, NNCF and NNC open design bearings, as well as sealed NNF design bearings (→ **fig. 17**). All bearings are non-separable and have an annular groove and three lubrication holes in the outer ring to facilitate lubrication. NNF design bearings have three additional lubrication holes in the inner ring.

### NNCL design

NNCL design bearings have three integral flanges on the inner ring and no flanges on the outer ring. A retaining ring inserted in the outer ring between the roller rows holds the bearing together. The retaining ring should not be loaded axially during operation. These bearings can accommodate axial displacement of the shaft relative to the housing in both directions.

### NNCF design

NNCF design bearings have three integral flanges on the inner ring and one on the outer ring to locate the shaft axially in one direction. A retaining ring inserted in the outer ring on the side opposite the integral flange holds the bearing together. The retaining ring should not be loaded axially during operation. These bearings are used to locate the shaft axially in one direction and eventually to accommodate axial displacement of the shaft relative to the housing in the opposite direction.

### NNC design

NNC design bearings have the same inner ring as NNCL and NNCF design bearings. The two-piece outer ring is held together by retaining elements, which should never be loaded axially. Both parts of the outer ring are identical and have one integral flange. These bearings are used to locate the shaft axially in both directions.

Fig. 17

## 5 Cylindrical roller bearings

### NNF design (sealed bearings)

NNF design bearings in the 50 and 3194.. series have a two-piece inner ring, held together by a retaining ring. The inner ring has three integral flanges and the outer ring has one integral central flange. The bearings are used to locate a shaft axially in both directions. The distance between the two rows of rollers enables these bearings to accommodate tilting moments.

The outer ring of an NNF design bearing is 1 mm narrower than the inner ring. In applications with a rotating outer ring, there is no need for spacer rings between the inner ring and adjacent components. The outer ring has two snap ring grooves to simplify installation and save space axially, when the bearing is mounted in/on an adjacent component, e.g. in rope sheaves (→ fig. 18).

The bearings have a contact PUR seal on both sides. Each seal is fitted in a recess on the inner ring shoulder (→ fig. 17 , page 579). The seal lip exerts slight pressure against the outer ring raceway. The bearings are filled with a high-quality grease with good rust inhibiting properties (→ table 1). For additional information about greases, refer to *Lubrication* (→ page 239).

For applications where oil lubrication is to be used, the bearings can be supplied open and without grease. If a small quantity of bearings without seals is required, the seals can be removed and the bearings can be washed prior to installation.

### Relubrication of sealed bearings

For many application conditions, sealed double row full complement cylindrical roller bearings do not require relubrication and can be considered relubrication-free (→ *Relubrication*, **page 252**). However, if they operate in a moist or contaminated environment, or if speeds are moderate to high, relubrication may be necessary. The bearings can be relubricated via lubrication holes in both the inner and outer rings.

### Matched bearings

SKF can supply matched bearings. To match bearings, SKF combines bearings so that the difference in cross-section height lies within a very small tolerance range. This reduced tolerance range is a precondition for equal load sharing between the bearings.

Matched bearings are identified by a designation suffix:

- DR for a set of two bearings
- TR for a set of three bearings
- QR for a set of four bearings

The bearings in a matched set can be single row or double row bearings. For additional information, contact the SKF application engineering service.

## 5 Cylindrical roller bearings

### Cages

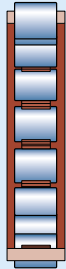

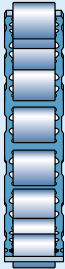

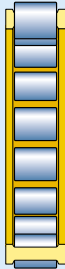

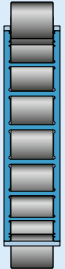

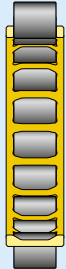

SKF single row and high-capacity cylindrical roller bearings are fitted, depending on their design, series and size, with one of the cages shown in **table 2**.

A large number of single row cylindrical roller bearings included in the SKF standard assortment are available as standard with more than one cage design (→ **product tables**).

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide

cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

## Performance classes

### SKF Explorer bearings

In response to the ever-demanding performance requirements of modern machinery, SKF developed the SKF Explorer performance class of rolling bearings.

SKF Explorer cylindrical roller bearings realized this substantial improvement in performance by optimizing the internal geometry and surface finish of all contact surfaces, combining the extremely clean and homogenous steel with a unique heat treatment, optimizing the roller end / flange contact area and applying an advanced logarithmic contact profile to the rollers and raceways.

These improvements provide the following benefits:

- higher dynamic load carrying capacity
- reduced edge loading
- improved wear-resistance
- reduced noise and vibration levels
- less frictional heat
- significantly extended bearing service life

SKF Explorer bearings reduce environmental impact by enabling downsizing and reducing both lubricant and energy consumption. Just as importantly, SKF Explorer bearings can reduce the need for maintenance and contribute to increased productivity.

SKF Explorer bearings are shown with an asterisk in the product tables. The bearings retain the designation of earlier standard bearings. However, each bearing and its box are marked with the name “SKF Explorer”.

Some cylindrical roller bearings are available as standard and as SKF Explorer bearings. Those SKF Explorer bearings are identified by the designation suffix PEX.

### SKF Energy Efficient (E2) bearings

To meet the ever-increasing demand to reduce friction and energy consumption, SKF has developed the SKF Energy Efficient (E2) performance class of rolling bearings. NJ design cylindrical roller bearings within this performance class that are axially loaded are characterized by a frictional moment in the bearing that is up to 85% lower when compared to a same-sized standard SKF bearing and an increased axial load carrying capacity (ratio  $F_a/F_r$  up to 0,6). The heavier the axial load, the higher the advantage in frictional moment compared to standard or SKF Explorer bearings.

Reduced operating temperatures improve lubrication conditions and enable extended lubrication intervals or higher speeds. The improved roller end / flange contact in the bearing reduces the risk of skidding and smearing. Typical applications include wind energy transmissions, industrial transmissions and other applications with combined loads.

SKF E2 single row cylindrical roller bearings are available in the NJ design on request. For additional information, contact the SKF application engineering service.

**Dynamic axial load carrying capacity**

Cylindrical roller bearings with flanges on both the inner and outer rings can support axial loads in addition to radial loads.  $F_a$  must not exceed 0,25  $F_r$  for double row full complement cylindrical roller bearings and 0,5  $F_r$  for other designs.

The axial load carrying capacity is primarily determined by the ability of the sliding surfaces of the roller end / flange contact to support loads. Factors having the greatest effect on this ability are the lubricant, operating temperature and the ability of the bearing to dissipate heat.

The formulae below are valid for normal operating conditions, i.e.:

- $\Delta T \approx 60 \text{ }^\circ\text{C}$  between the bearing operating and ambient temperature
- specific heat loss  $\approx 0,5 \text{ mW/mm}^2$
- viscosity ratio  $\kappa \geq 2$
- misalignment  $\leq 1$  minute of arc

For misalignment  $> 1$  minute of arc, contact the SKF application engineering service.

Surface of outside and bore diameter  $\pi B (D + d) \leq 50\,000 \text{ mm}^2$

$$F_{ap} = \frac{k_1 C_0 10^4}{n (d + D)} - k_2 F_r$$

Surface of outside and bore diameter  $\pi B (D + d) > 50\,000 \text{ mm}^2$

$$F_{ap} = \frac{7,5 k_1 C_0^{2/3} 10^4}{n (d + D)} - k_2 F_r$$

Circulating oil applications

$$F_{ap \text{ oil}} = F_{ap} + \frac{1,5 \times 10^4 k_1 \Delta T_s V_s}{n (d + D)}$$

To avoid any risk of flange fracture, the maximal constantly acting axial load is limited:

Bearings in the 2.. series  
 $\rightarrow F_{ap \text{ max}} \leq 0,0045 D^{1,5}$   
 Other series  
 $\rightarrow F_{ap \text{ max}} \leq 0,0023 D^{1,7}$

For brief periods, provided it does not increase the bearing operating temperature  $> 5 \text{ }^\circ\text{C}$  temporarily:

$$F_{ap \text{ brief}} \leq 2 F_{ap} \quad \text{where } F_{ap} = F_{ap}, F_{ap \text{ oil}} \text{ or } F_{ap \text{ max}}$$

Depending on the bearing size, load and speed, this “brief period” covers only several seconds or can last a few minutes. As rule of thumb it can be assumed that a “brief period” is the time it takes for the bearing to make 1 000 revolutions.

Occasional shock loads:

$$F_{ap \text{ shock}} \leq 3 F_{ap} \quad \text{where } F_{ap} = F_{ap}, F_{ap \text{ oil}} \text{ or } F_{ap \text{ max}}$$

### Flange support

When cylindrical roller bearings are subjected to heavy axial loads, axial run-out and the size of the abutment surfaces of adjacent components are particularly important for running accuracy and even load distribution on the flange.

The inner ring flange should only be supported up to half of its height (→ **fig. 19**) so that it is not subjected to damaging alternating stresses that can result, for example from shaft deflection.

For single row cylindrical roller bearings and high-capacity cylindrical roller bearings, the recommended shaft abutment diameter can be obtained using

$$d_{as} = 0,5 (d_1 + F)$$

where

$d_{as}$  = shaft abutment diameter for axially loaded bearings [mm]

$d_1$  = inner ring flange diameter [mm]

$F$  = inner ring raceway diameter [mm]

For full complement cylindrical roller bearings the recommended shaft abutment diameter  $d_{as}$  is listed in the product tables.

Fig. 19

## Temperature limits

The permissible operating temperature for cylindrical roller bearings can be limited by:

- the dimensional stability of the bearing rings and rollers
- the cage
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing rings and rollers

SKF cylindrical roller bearings undergo a special heat treatment. The bearing rings and rollers are heat stabilized up to at least 150 °C (300 °F).

### Cages

Steel, brass or PEEK cages can be used at the same operating temperatures as the bearing rings and rollers. For temperature limits of cages made of other polymer materials, refer to *Cage materials* (→ **page 152**).

### Seals

The permissible operating temperature for PUR seals is –20 to +80 °C (–5 to 175 °F).

### Lubricants

Temperature limits for the greases used in sealed double row full complement cylindrical roller bearings are provided in **table 1** (→ **page 580**). Temperature limits for other SKF greases are provided under *Lubrication* (→ **page 239**).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

## Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**). If no reference speed is listed in the product tables, the limiting speed is the permissible speed.

SKF recommends oil lubrication for bearings with a ring centred cage. When these bearings are grease lubricated (→ *Lubrication, Cylindrical roller bearings*, **page 254**) the speed factor is limited:

- for bearings with an MA, MB, MH, ML, MP, JA or JB cage  
→  $A \leq 250\,000 \text{ mm/min}$
- for bearings with a PA or PHA cage  
→  $A \leq 450\,000 \text{ mm/min}$

where

$$A = n d_m [\text{mm/min}]$$

$$d_m = \text{bearing mean diameter [mm]} \\ = 0,5 (d + D)$$

$$n = \text{rotational speed [r/min]}$$

For applications exceeding these values, contact the SKF application engineering service.

For single row bearings with a standard cage, the values for the limiting speed are listed in the product tables. Conversion factors to estimate the limiting speed for bearings with an alternative standard cage are listed in **table 9**.

The values for the reference speed listed in the product tables for sealed double row full complement bearings are valid for grease lubricated open bearings (i.e. seals removed from the bearings) and demonstrate the speed capability of these bearings. If oil lubrication is used, the limiting speeds of open NNF design bearings, listed in the product tables can be increased by  $\approx 30\%$ .

## Mounting

### Interchangeable components

The separable components of same-size SKF cylindrical roller bearings are fully interchangeable, if the bearings are in the same internal clearance class.

### High-capacity cylindrical roller bearings

Due to the design and position of the cage of high-capacity cylindrical roller bearings in the NCF .. ECJB and NJF .. ECJA series, the cage cannot prevent the rollers from falling out when the inner and outer rings of the bearing are separated. SKF recommends mounting these high-capacity cylindrical roller bearings as a complete bearing, like full complement cylindrical roller bearings.

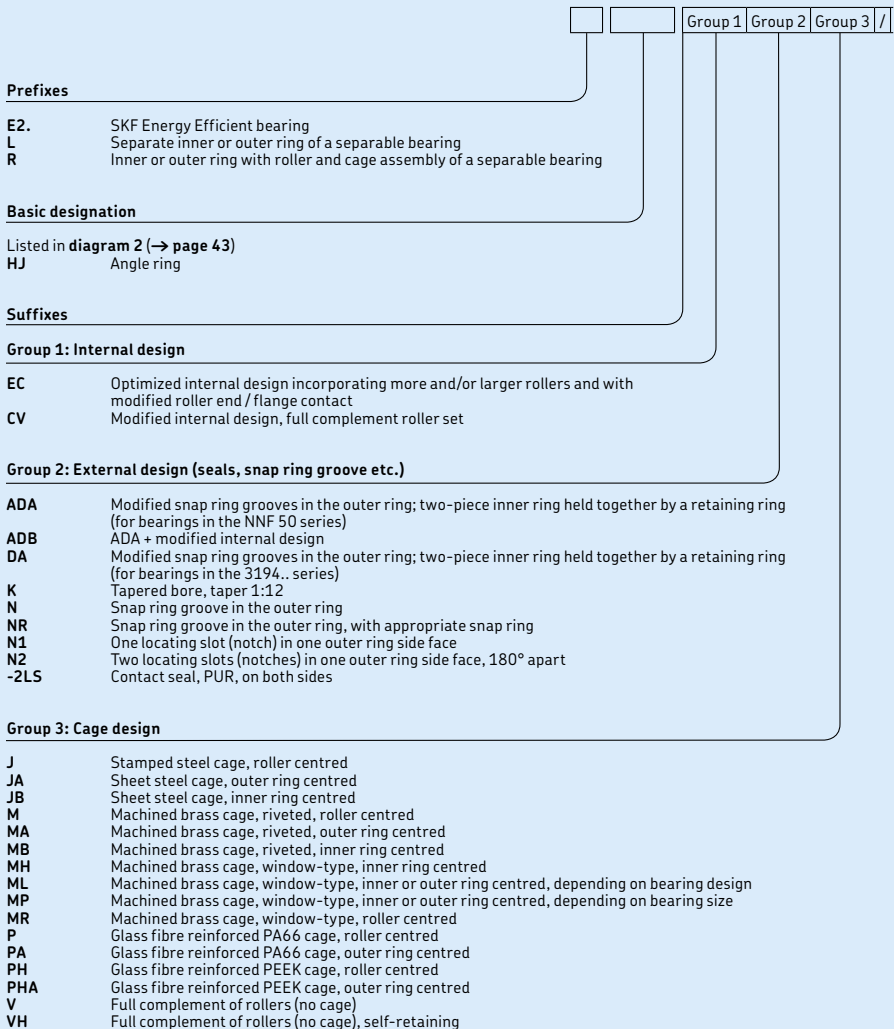

If it is necessary to mount the inner and outer rings separately use a mounting sleeve or a retaining strap to keep the rollers in place (→ fig. 20).

### Single row full complement cylindrical roller bearings, NJG design

NJG design bearings are separable. The outer ring together with the roller complement can be mounted independently from the inner ring without special precautions to prevent the rollers from falling out. The bearings have a self-retaining roller complement.

Group 4					
4.1	4.2	4.3	4.4	4.5	4.6

**Group 4.6: Other variants**

- PEX** SKF Explorer bearing, used only when same-sized conventional and SKF Explorer bearings are available
- VA301** Bearing for railway vehicle traction motors
- VA305** VA301 + special inspection routines
- VA350** Bearing for railway axleboxes
- VA380** Bearing for railway axleboxes in accordance with EN 12080, class 1
- VA3091** VA301 + external surfaces of the outer ring are coated with aluminium oxide
- VC025** Bearing with special wear-resistant raceways for applications in heavily contaminated environments
- VQ015** Inner ring with crowned raceway for increased permissible misalignment

**Group 4.5: Lubrication**

**Group 4.4: Stabilization**

- S1** Bearing rings heat stabilized for operating temperatures  $\leq 200\text{ }^{\circ}\text{C}$  ( $390\text{ }^{\circ}\text{F}$ )
- S2** Bearing rings heat stabilized for operating temperatures  $\leq 250\text{ }^{\circ}\text{C}$  ( $480\text{ }^{\circ}\text{F}$ )

**Group 4.3: Bearing sets, matched bearings**

- DR** Two bearings matched to one set
- TR** Three bearings matched to one set
- QR** Four bearings matched to one set

**Group 4.2: Accuracy, clearance, preload, quiet running**

- CN** Normal radial internal clearance; only used together with an additional letter that identifies a reduced or displaced clearance range
  - H** Reduced clearance range corresponding to the upper half of the actual clearance range
  - L** Reduced clearance range corresponding to the lower half of the actual clearance range
  - M** Reduced clearance range corresponding to the middle half of the actual clearance range
 The above letters are also used together with the clearance classes C2, C3, C4 and C5, e.g. C2H
- C2** Radial internal clearance smaller than Normal
- C3** Radial internal clearance greater than Normal
- C4** Radial internal clearance greater than C3
- C5** Radial internal clearance greater than C4

**Group 4.1: Materials, heat treatment**

- HA1** Case-hardened inner and outer rings
- HA3** Case-hardened inner ring
- HB1** Bainite-hardened inner and outer rings
- HN1** Inner and outer rings with special surface heat treatment
- L4B** Bearing rings and rollers black oxidized
- L5B** Rollers black oxidized
- L7B** Inner ring and rollers black oxidized

## Designs and variants

SKF needle roller bearings are bearings with cylindrical rollers that are small in diameter relative to their length. The ends of the rollers are relieved slightly to modify the line contact between the rollers and raceways. This prevents stress peaks at the roller ends to extend bearing service life. In spite of their low cross section, needle roller bearings have a high load carrying capacity. Therefore, they are extremely suitable for bearing arrangements where radial space is limited. SKF supplies needle roller bearings in many different designs, series and in a wide range of sizes, which make them appropriate for a wide variety of operating conditions and applications.

## Needle roller and cage assemblies

SKF needle roller and cage assemblies are ready-to-mount, self-contained bearings. They are an excellent choice for applications that require a very rigid bearing arrangement as well as a high load carrying capacity. If the shaft and housing bore can serve as raceways, needle roller and cage assemblies require minimal radial space.

### Basic design bearings

SKF basic design needle roller and cage assemblies are identified by the series designation K and available in single row (no designation suffix) and double row (designation suffix ZW) designs (→ **fig. 1**). They are characterized by the following properties:

- simple and rugged design
- accurate roller guidance in the cage pockets
- good running performance

### Other needle roller and cage assemblies

On request, SKF also supplies needle roller and cage assemblies in other sizes or different designs.

Needle roller and cage assemblies with a split cage can be used where raceways are recessed in the shaft (→ **fig. 2**).

Fig. 2

## 6 Needle roller bearings

Special needle roller and cage assemblies for the gudgeon (wrist) pin (→ **fig. 3**) and crank pin (crankshaft journal) (→ **fig. 4**) for connecting rods of internal combustion engines and compressors, provide excellent service in spite of rapid accelerations, elevated temperatures, unfavourable load or poor lubrication conditions.

For additional information about special sizes and designs of needle roller and cage assemblies, contact the SKF application engineering service.

### Drawn cup needle roller bearings

SKF drawn cup needle roller bearings have a deep drawn, thin-walled outer ring. They are characterized by a very low sectional height and high load carrying capacity. Drawn cup needle roller bearings are typically used in applications where the housing bore cannot be used as a raceway for a needle roller and cage assembly, but where a very compact and economical bearing arrangement is required. These bearings are mounted with a tight interference fit in the housing. That enables a simple and economic design of the housing bore, as shoulders or snap rings are not required to locate the bearing axially.

The drawn cup of hardened steel and the needle roller and cage assembly of these bearings form a non-separable unit.

SKF supplies a wide assortment of drawn cup needle roller bearings. This includes:

- drawn cup needle roller bearings with open ends (→ **fig. 5**)
- drawn cup needle roller bearings with a closed end (→ **fig. 6**)
- full complement drawn cup needle roller bearings with open ends (→ **fig. 7**)

## 6 Needle roller bearings

SKF supplies all drawn cup needle roller bearings without an inner ring. These bearings are generally designed with one needle roller and cage assembly. However, wide sizes incorporate two needle roller and cage assemblies immediately adjacent to each other, with a lubrication hole in the outer ring (→ **fig. 8**). The double row bearings are not identified by any designation suffix but are marked in the product tables by a footnote.

### Drawn cup needle roller bearings with open ends

SKF drawn cup needle roller bearings with open ends (→ **fig. 5, page 677**) are identified by the series designation HK. They are available open (without seals) or sealed on one or both sides (→ *Sealing solutions, page 696*).

### Drawn cup needle roller bearings with a closed end

SKF drawn cup needle roller bearings with a closed end (→ **fig. 6, page 677**) are identified by the series designation BK. They are available open or sealed (→ *Sealing solutions, page 696*) and are suitable for bearing arrangements at the end of a shaft. The profiled design of the closed end accommodates small axial guidance forces.

### Full complement drawn cup needle roller bearings

SKF full complement drawn cup needle roller bearings (→ **fig. 7, page 677**) are identified by the series designation HN. They are suitable for very heavy radial loads at moderate speeds and are available with open ends and without seals only.

Fig. 8

HK (double row)

**Greases for full complement drawn cup bearings**

Full complement drawn cup needle roller bearings are supplied with a special grease to secure the rollers during transport. However, SKF recommends relubricating after mounting, as this grease does not provide sufficient long term lubrication. Depending on the required consistency class, SKF recommends SKF LGEP 2 or SKF LGMW 1 grease for relubrication. The technical specifications of the initial grease fill and the relubrication greases are listed in **table 1**.

**Arrangements with components and other bearings**

Generally, drawn cup needle roller bearings run directly on a shaft. However, in applications where the shaft cannot be hardened and ground, bearings should be combined with an inner ring (→ **fig. 9**). Wide inner rings can also provide an excellent counterface for the lips of external G or SD design seals (→ [skf.com/seals](http://skf.com/seals)). For additional information about inner rings, refer to *Needle roller bearing inner rings* (→ **page 691**).

To accommodate combined radial and axial loads, certain sizes of drawn cup needle roller bearings can be combined with a needle roller thrust bearing with a centring flange, AXW series (→ **fig. 10**). For additional information, refer to *Needle roller thrust bearings* (→ **page 1057**).

## 6 Needle roller bearings

### Needle roller bearings with machined rings

SKF needle roller bearings with machined rings are made of carbon chromium bearing steel. Relative to their low sectional height, they have a high load carrying capacity. SKF supplies needle roller bearings with machined rings with (→ **fig. 11**) or without flanges (→ **fig. 12**) on the outer ring, in a wide range of series and sizes. SKF also supplies these bearings with or without an inner ring.

### Needle roller bearings with machined inner and outer rings

Needle roller bearings with an inner ring (→ **fig. 12**) are used for applications where the shaft cannot be hardened and ground. The permissible axial displacement (→ **product tables**) of the shaft relative to the housing is limited for bearings with an inner ring. If the permissible axial displacement provided by a standard inner ring is insufficient, it is possible to use an extended inner ring (→ *Needle roller bearing inner rings*, **page 691**).

### Needle roller bearings with a machined outer ring, without an inner ring

Needle roller bearings without an inner ring (→ **fig. 11**) are an excellent choice for compact bearing arrangements if the shaft can be hardened and ground. Eliminating the need for a separate inner ring enables a larger shaft diameter and a stiffer bearing arrangement. Axial displacement of the shaft relative to the housing is only limited by the width of the raceway on the shaft. By machining the shaft raceways to the appropriate dimensional and geometrical accuracy, it is possible to obtain bearing arrangements with heightened running accuracy. For additional information, refer to *Raceways on shafts and in housings* (→ **page 210**).

Fig. 11

Fig. 12

### Needle roller bearings with machined rings, with flanges

SKF needle roller bearings with flanges on the outer ring are available open (without seals) or sealed (→ *Sealing solutions*, page 696) on one or both sides and with or without an inner ring. Bearings with an outside diameter  $D \leq 17$  mm ( $F_w \leq 10$  mm), are available with non-separable closure rings that act as flanges (→ **fig. 13**). The flanges on larger bearings are an integral part of the outer ring, and the bearings have an annular groove and one or more lubrication holes in the outer ring (→ **fig. 14**). With the exception of RNA 69 (→ **fig. 15**) and NA 69 series double row bearings with an outside diameter  $D \geq 52$  mm ( $F_w \geq 40$  mm), needle roller bearings with flanges are generally designed as single row bearings.

The roller and cage assembly and outer ring of a needle roller bearing with flanges form a non-separable unit.

## 6 Needle roller bearings

### Needle roller bearings with machined rings, without flanges

SKF needle roller bearings without flanges on the outer ring are separable, i.e. the outer ring, needle roller and cage assembly and inner ring, can all be mounted separately. Therefore, the needle roller and cage assembly can either be mounted together with the outer ring or with the shaft or inner ring, depending on the arrangement design. It can also be inserted between the outer ring and shaft or inner ring as the final step. However, needle roller and cage assemblies and bearing outer rings must always be kept together as supplied.

SKF needle roller bearings without flanges are generally designed with one needle roller and cage assembly (→ **fig. 12, page 680**). However, wide sizes incorporate two needle roller and cage assemblies immediately adjacent to each other and have an annular groove and a lubrication hole in the outer ring (→ **fig. 16**). The double row bearings are not identified by any designation suffix, but are marked in the product tables by a footnote.

### Arrangements with other bearings

To accommodate combined radial and axial loads, needle roller bearings with machined rings can be combined with a needle roller thrust bearing with a centring flange, AXW series, if the outside diameter  $D$  of the radial bearing is equal to the flange diameter  $D_1$  of the thrust bearing (→ **fig. 17**). For additional information, refer to *Needle roller thrust bearings* (→ **page 1057**).

Fig. 16

Fig. 17

### Alignment needle roller bearings

SKF alignment needle roller bearings have an outer ring with a sphered (convex) outside surface. Two polymer seating rings with a sphered (concave) inside surface are encased in a drawn sheet steel sleeve and fitted over the outer ring. This design enables the bearing to accommodate static misalignment of the shaft relative to the housing. SKF supplies alignment needle roller bearings with or without an inner ring (→ **fig. 18**). Sealed variants are not available.

In applications where the shaft cannot be hardened and ground, bearings with an inner ring should be used. The permissible axial displacement (→ **product tables**) of the shaft relative to the housing is limited for bearings with an inner ring. If the permissible axial displacement provided by a standard inner ring is insufficient, it is possible to use an extended inner ring (→ *Needle roller bearing inner rings*, **page 691**).

Bearings without an inner ring are an excellent choice for compact bearing arrangements, if the shaft can be hardened and ground.

### Combined needle roller bearings

SKF combined needle roller bearings consist of a radial needle roller bearing combined with a thrust bearing. They can accommodate both radial and axial loads. Combined needle roller bearings provide the means to design locating bearing arrangements where radial space is limited. They are particularly suitable for applications where other types of locating bearing arrangements occupy too much space, or where the axial loads are too heavy, the speeds are too high, or the lubricant is inadequate for arrangements with simple thrust washers. SKF supplies combined needle roller bearings in the following basic designs:

- needle roller / angular contact ball bearing
- needle roller / thrust ball bearing
- needle roller / cylindrical roller thrust bearing

Relubrication intervals for the radial and thrust part of the bearing must be calculated separately. The shorter of the two intervals should be used. For additional information about lubrication, refer to *Lubrication* (→ **page 239**).

6

## 6 Needle roller bearings

### Needle roller / angular contact ball bearings

SKF needle roller / angular contact ball bearings combine a radial needle roller bearing with an angular contact ball bearing. The radial loads are accommodated exclusively by the needle roller bearing and the axial loads exclusively by the angular contact ball bearing. These low cross section bearings can operate at high speeds and accommodate heavy radial and light axial loads. SKF supplies these bearings without seals in the following two series:

- NKIA series (→ **fig. 19**), bearings can accommodate axial loads in one direction
- NKIB series (→ **fig. 20**), bearings can accommodate axial loads in both directions

Bearings in both series are separable i.e. the inner ring can be mounted separately from the outer ring, rolling element and cage assemblies. However, the inner rings in the NKIB series are not interchangeable with those from another seemingly identical bearing. Therefore, the bearings must be kept together as supplied.

Depending on the application, needle roller / angular contact ball bearings can be grease or oil lubricated. In the case of grease lubrication, both the needle roller and angular contact ball bearing should be filled with the same lubricant prior to mounting.

Fig. 19

NKIA 59

Fig. 20

NKIB 59

Fig. 21

NKIA 59, back-to-back arrangement

**NKIA series**

Needle roller / angular contact ball bearings in the NKIA 59 series (→ **fig. 19**) can accommodate axial loads in one direction and can, therefore, locate the shaft in one direction only. For short shafts and where changes in length as a result of thermal expansion are relatively minor, two bearings in the NKIA 59 series can be mounted back-to-back (→ **fig. 21**).

**NKIB series**

Needle roller / angular contact ball bearings in the NKIB 59 series (→ **fig. 20**) can locate a shaft in both directions. Depending on the bearing size, the axial clearance is between 0,08 and 0,25 mm. To facilitate mounting, the bearing has a two-piece inner ring. When mounting the inner ring, it is important that the two pieces are mounted immediately adjacent to each other without any gap between them.

**Needle roller / thrust ball bearings**

SKF needle roller / thrust ball bearings combine a radial needle roller bearing and a thrust ball bearing. SKF supplies these bearings in the following two series:

- NX series (→ **fig. 22**), with a full complement thrust ball bearing
- NKX series (→ **fig. 23**), with a thrust ball bearing with a cage

Fig. 22

Fig. 23

## 6 Needle roller bearings

SKF supplies the bearings of both series without an inner ring. In applications where the shaft cannot be hardened and ground, the needle roller bearing can be combined with an inner ring (→ **fig. 24**). Appropriate inner rings are listed in the product tables and must be ordered separately.

Needle roller / thrust ball bearings can accommodate axial loads in one direction and can, therefore, locate the shaft in one direction only. For short shafts and where changes in length as a result of thermal expansion are relatively minor, two bearings can be mounted back-to-back (→ **fig. 25**). For these types of arrangements, SKF recommends elastically preloading the thrust ball bearings with cup springs (Belleville washers). This elastic preload helps to prevent the balls from skidding if one of the thrust bearings becomes unloaded. Preload also improves performance of the thrust ball bearings while reducing noise levels.

Fig. 24

NX with an inner ring

Fig. 25

NKX, back-to-back arrangement, incorporating Belleville washers

**NX series**

Needle roller / full complement thrust ball bearings in the NX series (→ **fig. 26**) are suitable for applications where there are moderate radial loads and lighter, single direction axial loads. Their extremely low sectional height enables shaft centrelines to be positioned close together like for multi-spindle drills. For axial support, the bearings can be mounted with a snap ring or against a shoulder in the housing bore. The snap ring groove in the outer ring provides a cost-effective and axially space-saving solution (→ **fig. 27**). The appropriate snap rings are listed in the product tables.

Needle roller / thrust ball bearings in the NX series have a stamped steel cover. It extends over the shaft washer of the thrust ball bearing and is firmly attached to the radial needle roller bearing. The cover makes these bearings non-separable. Most often they are oil lubricated, as the cover has lubrication holes. Therefore, SKF supplies these bearings without grease.

Needle roller / thrust ball bearings in the NX series with the designation suffix Z (→ **fig. 28**) have a stamped steel cover without lubrication holes and should be grease lubricated.

Fig. 26

NX

Fig. 27

## 6 Needle roller bearings

### NKX series

Needle roller / thrust ball bearings in the NKX series combine a radial needle roller bearing and a thrust ball bearing with a ball and cage thrust assembly identical to the 511 series. They permit relatively high-speed operation. The outer ring flange locates the bearings axially in one direction.

Needle roller / thrust ball bearings in the NKX series (→ **fig. 29**) do not have a cover over the thrust ball bearing. Therefore, both the ball and cage assembly and shaft washer can be mounted separately from the rest of the bearing. These bearings, without the designation suffix Z, should be oil lubricated whenever possible, as there is no cover that retains the grease in the bearing.

Needle roller / thrust ball bearings in the NKX series with the designation suffix Z (→ **fig. 30**) have a stamped steel cover without lubrication holes. The steel cover extends over the shaft washer of the thrust ball bearing. It is firmly attached to the housing washer that is integral to the needle roller bearing outer ring. The cover makes these bearings non-separable.

Fig. 29

NKX

Fig. 30

NKX..Z

### Needle roller / cylindrical roller thrust bearings

SKF needle roller / cylindrical roller thrust bearings in the NKXR series (→ **fig. 31**) combine a radial needle roller bearing and a cylindrical roller thrust bearing. The cylindrical roller and cage thrust assembly is identical to the 811 series. These combined bearings are supplied without an inner ring. In applications where the shaft cannot be hardened and ground, bearings can be combined with an inner ring (→ **fig. 32**). Appropriate inner rings are listed in the product tables and must be ordered separately.

Needle roller / cylindrical roller thrust bearings in the NKXR series are separable. Both the cylindrical roller and cage thrust assembly and shaft washer can be mounted separately from the rest of the bearing. These bearings, without the designation suffix Z, should be oil lubricated whenever possible, as oil facilitates an adequate supply of lubricant to the bearing.

Needle roller / cylindrical roller thrust bearings with the designation suffix Z (→ **fig. 33**) have a stamped steel cover without lubrication holes. The steel cover extends over the shaft washer of the cylindrical roller thrust bearing. It is firmly attached to the housing washer that is integral to the needle roller bearing outer ring. The cover makes these bearings non-separable.

## 6 Needle roller bearings

Needle roller / cylindrical roller thrust bearings can accommodate axial loads in one direction and can, therefore, locate the shaft in one direction only. For short shafts and where changes in length as a result of thermal expansion are relatively minor, two bearings can be mounted back-to-back (→ **fig. 34**). For these types of arrangements, SKF recommends elastically preloading the roller thrust bearings with cup springs (Belleville washers). This elastic preload helps to prevent the rollers from skidding if one of the thrust bearings becomes unloaded. Preload also improves the performance of the bearings while reducing noise levels.

## Needle roller bearing components

### Needle roller bearing inner rings

SKF supplies inner rings for needle roller bearings separately. They are typically combined with needle roller and cage assemblies or drawn cup needle roller bearings in applications where the shaft cannot be hardened and ground. Inner rings are available in the following two series:

- IR series (→ **fig. 35**), with or without a lubrication hole, with or without a machining allowance
- LR series (→ **fig. 36**)

Inner rings in both series are also available in different widths. Wide inner rings permit greater axial displacement of the shaft, relative to the housing, when compared to standard width inner rings. They also provide an excellent counterface for the lips of contact seals (→ **fig. 9, page 679**).

Regardless of whether the ring has an interference or loose fit, it should be located on both sides to prevent axial movement. One side can be located against a shoulder. The other side can be located by either a snap ring, a distance ring or a nut.

#### IR series

IR series inner rings, (→ **fig. 35**) the standard SKF inner rings for needle roller bearings, are made of carbon chromium bearing steel. The rings are hardened and ground. The raceway surface is precision ground, and has a lead-in chamfer on both sides. The chamfers facilitate assembly and protect the seal lips from damage during the mounting process.

Fig. 35

IR

Fig. 36

LR

## 6 Needle roller bearings

Some sizes of IR inner rings have a lubrication hole (→ **fig. 37**). They are identified by the designation suffix IS1. Inner rings with additional lubrication holes are available on request.

Also on request, SKF supplies inner rings in the IR series with a pre-ground raceway and a machining allowance  $z$ . These inner rings are identified by the designation suffix VGS. The machining allowance depends on the inner ring raceway diameter and is listed in **table 2**. They can be finish ground after mounting on a shaft in applications where extremely high running accuracy is required.

### LR series

Inner rings in the LR series (→ **fig. 36**, **page 691**) are made of carbon chromium bearing steel. The rings are hardened, and the bore and raceway diameter are ground. The side faces are turned and the edges are smoothed. For applications where the larger run-out and width tolerances are less important, these inner rings can be used to provide a cost-effective bearing arrangement.

### Needle rollers

SKF needle rollers are made of carbon chromium steel. The rollers have a hardness of 58 to 65 HRC and have a precision ground surface. They can be used to design full complement bearing arrangements for slow-speed or oscillating applications. These compact bearing arrangements have a very high load carrying capacity when compared to bearings with a cage and are economical, provided the shaft and housing bore can serve as raceways (→ *Raceways on shafts and in housings*, **page 210**).

For assistance in designing full complement bearing arrangements or to calculate performance data for these bearing arrangements, contact the SKF application engineering service.

## Cages

Depending on their design, series and size, SKF needle roller bearings are fitted with one of the cages shown in **table 3** (→ **page 694**). The standard cage is not identified in the bearing designation.

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

### Double row needle roller bearings

Double row needle roller and cage assemblies have a double row cage in the same design as a single row cage (→ **fig. 1, page 675**).

Other double row needle roller bearings are equipped with two cage assemblies (→ **fig. 15, page 681** and **fig. 16, page 682**).

## 6 Needle roller bearings

### Sealing solutions

SKF supplies certain needle roller bearings capped with a seal or steel cover. The assortment of capped bearings includes the following types:

- drawn cup needle roller bearings, sealed on one or both sides
- needle roller bearings with machined rings in the (R)NA 49 series, sealed on one or both sides
- combined needle roller bearings with the designation suffix Z, steel cover over the thrust part of the bearing

SKF supplies capped bearings filled, as standard, with high-quality grease that has good corrosion inhibiting properties (→ *Greases for capped bearings*, page 698).

In addition to integral bearing seals, SKF also supplies an assortment of external seals that can be used for needle roller bearing arrangements. Appropriate power transmission seals are listed in the relevant product tables, when available. For information about these seals, refer to the product information, available online at [skf.com/seals](http://skf.com/seals).

#### Sealed drawn cup needle roller bearings

For applications where a sufficiently effective seal is not available, or cannot be used for space reasons, SKF supplies certain drawn cup needle roller bearings as sealed bearings. They include:

- drawn cup needle roller bearings with open ends, sealed on one side, designation suffix RS (→ **fig. 38**), available for shaft diameters ranging from 8 to 50 mm
- drawn cup needle roller bearings with open ends, sealed on both sides, designation suffix .2RS (→ **fig. 39**), available for shaft diameters ranging from 8 to 50 mm
- sealed drawn cup needle roller bearings with a closed end, designation suffix RS (→ **fig. 40**), available for shaft diameters ranging from 10 to 25 mm

These integral contact seals are made of PUR, FKM or NBR. Sealed drawn cup needle roller bearings are, under normal conditions, an extremely cost-effective solution to exclude

Fig. 38

HK..RS

Fig. 39

HK...2RS

Fig. 40

solid contaminants and moisture and retain the lubricant in the bearing.

#### Sealed needle roller bearings with machined rings

Needle roller bearings with machined rings in the (R)NA 49 series are available with a contact seal (→ **fig. 41**) on one or both sides. The NBR seals are effective at keeping the lubricant in and contaminants out of the bearing.

The inner ring of sealed bearings is 1 mm wider than the outer ring. This maintains the effectiveness of the seals and simplifies the bearing arrangements even when small axial displacements occur.

#### WARNING

Seals made of FKM (fluoro rubber) exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions under *Seal materials* (→ **page 155**).

Fig. 41

## 6 Needle roller bearings

### Combined needle roller bearings, designation suffix Z

Combined needle roller bearings with the designation suffix Z have a stamped steel cover over the thrust part of the bearing. The cover, which has no lubrication holes, forms a gap-type seal to retain the grease in the bearing. They are available in the following basic designs and series:

- needle roller / thrust ball bearing, NX .. Z (→ **fig. 28, page 687**) and NKX .. Z (→ **fig. 30, page 688**) series
- needle roller / cylindrical roller thrust bearing, NKXR .. Z series (→ **fig. 33, page 689**)

### Greases for capped bearings

Needle roller bearings with one or two seals are supplied greased. The thrust part of combined needle roller bearings with the designation suffix Z is also supplied greased. They are filled with high-quality grease under clean conditions.

The relatively large quantity of grease in the bearings means they can be operated for long periods before relubrication is required. SKF recommends SKF LGWA 2 grease, if relubrication is required.

The technical specifications for the initial grease fill and the grease for relubrication are listed in **table 4**.

## Relubrication facilities

Depending on the design and size, SKF supplies needle roller bearings with different features to facilitate efficient lubrication and relubrication.

### Drawn cup needle roller bearings

SKF supplies all double row drawn cup bearings with one lubrication hole in the outer ring (→ **fig. 8, page 678**), as standard.

On request, SKF can supply any single row drawn cup needle roller bearing for inside diameters under the rollers  $F_w \geq 7$  mm with a lubrication hole in the outer ring (→ **fig. 42**).

### Needle roller bearings with machined rings

All needle roller bearings with machined rings and flanges, with an outside diameter  $D \geq 19$  mm ( $F, F_w \geq 12$  mm) have an annular groove and, depending on the bearing size, one or more lubrication holes in the outer ring (→ **fig. 14, page 681**).

Sealed needle roller bearings have one lubrication hole in the inner ring (→ **fig. 41, page 697**).

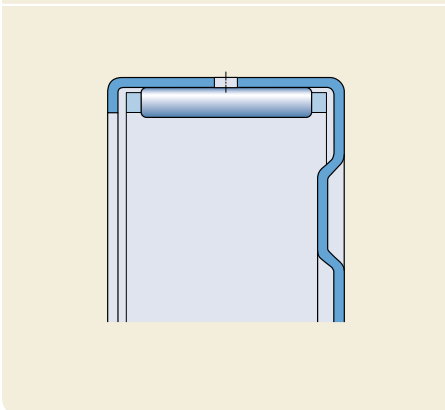

Double row machined needle roller bearings without flanges also have an annular groove with one lubrication hole in the outer ring (→ **fig. 15, page 681**). To provide efficient relubrication for double row bearings without flanges and with an inner ring, SKF supplies certain sizes with one lubrication hole in the inner ring. They are not identified by any designation suffix but are marked in the product tables by a footnote.

### Combined needle roller bearings

The needle roller bearing of all combined bearings has an annular groove with one lubrication hole in the outer ring.

Needle roller / full complement thrust ball bearings in the NX series without the designation suffix Z have a cover with lubrication holes over the thrust part of the bearing (→ **fig. 24, page 686**). Most often they are oil lubricated and, therefore, SKF supplies these bearings without grease.

### Temperature limits

The permissible operating temperature for needle roller bearings can be limited by:

- the dimensional stability of the bearing rings and rollers
- the cages
- the seals
- the seating rings
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

#### Bearing rings and rollers

SKF needle roller bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 120 °C (250 °F).

Drawn cup needle roller bearings are heat stabilized up to at least 140 °C (285 °F).

#### Cages

Steel cages can be used at the same operating temperatures as the bearing rings and rollers. For temperature limits of polymer cages, refer to *Cage materials* (→ page 152).

#### Seals

The permissible operating temperature for seals depends on the material:

- NBR seals:  
–40 to +100 °C (–40 to +210 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- PUR seals:  
–30 to +100 °C (–20 to +210 °F)
- FKM seals:  
–30 to +200 °C (–20 to +390 °F)

#### Seating rings

The permissible operating temperature for seating rings fitted to alignment needle roller bearings is –30 to +100 °C (–20 to +210 °F).

#### Lubricants

Temperature limits for the grease used in capped needle roller bearings are provided in **table 4** (→ page 698) and for full complement drawn cup needle roller bearings in **table 1** (→ page 679). Temperature limits for other

SKF greases are provided under *Lubrication* (→ page 239).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ page 244).

### Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ page 117). If no reference speed is listed in the product tables, the limiting speed is the permissible speed.

### Design of bearing arrangements

#### Abutment dimensions

##### Needle roller and cage assemblies

Needle roller and cage assemblies should be guided axially by the fine turned and polished surfaces of adjacent machine components. For high-speed operations they should be hardened and ground. Appropriate abutment diameters are provided in **table 14**.

Interruptions in the surface of adjacent machine components should be avoided. Snap rings can be used in less demanding applications, otherwise an intermediate ring, e.g. a spring steel washer, should be mounted between the snap ring and the cage assembly.

##### Needle roller bearings with machined rings, without flanges

The cage of needle roller bearings without flanges should be guided axially by the fine turned and polished surfaces of adjacent machine components. Appropriate abutment diameters are listed in the product tables.

Table 14

25	65	$E_w - 0,5$	$F_w + 0,5$
65	-	$E_w - 1$	$F_w + 1$

### Combined needle roller bearings

The diameter of the thrust bearing support surface in the housing should be at least 0,5 mm larger than the dimension  $D_1$  or  $D_2$  (→ **fig. 43**). The values for the diameters  $D_1$  and  $D_2$  for needle roller / thrust ball bearings and needle roller / cylindrical roller thrust bearings are listed in the product tables.

### Shaft and housing tolerances

The following tables provide tolerance classes to obtain suitable fits and an appropriate operating clearance (→ *Operating clearance*, page 700) for the following needle roller bearing types:

- drawn cup needle roller bearings
- needle roller bearings with machined inner and outer rings
- alignment needle roller bearings
- combined needle roller bearings

The tolerances of raceways on shafts and in housings for needle roller and cage assemblies and of raceways on shafts for machined needle roller bearings without an inner ring, significantly influence the operating clearance of the bearing and, therefore, are provided under *Operating clearance* (→ page 700).

For additional information about the tolerances, refer to *Raceways on shafts and in housings* (→ page 210).

<sup>1)</sup> All ISO tolerance classes are valid with the envelope requirement (such as H7(Ⓔ)) in accordance with ISO 14405-1.

<sup>2)</sup> For drawn cup needle roller bearings that are mounted in housings that are not rigid, the shaft tolerance giving the desired radial clearance must be determined by trial and error.

<sup>3)</sup> The geometrical accuracy in accordance with ISO 1101 for the housing bore of drawn cup needle roller bearings must correspond to IT5/2 tolerance grade.

### Drawn cup needle roller bearings

**Table 15** provides suitable tolerance classes for the housing bore and shaft for drawn cup needle roller bearings with or without an inner ring.

### Needle roller bearings with machined rings

**Table 16** provides suitable tolerance classes for the shaft for needle roller bearings with machined inner and outer rings.

The recommended housing fits for needle roller bearings with machined inner and outer rings are provided in **tables 4 and 5** (→ **pages 174 and 175**).

### Alignment needle roller bearings

<sup>1)</sup> All ISO tolerance classes are valid with the envelope requirement (such as h7(Ⓔ)) in accordance with ISO 14405-1.

<sup>2)</sup> Bearings with radial internal clearance greater than Normal may be necessary.

### Combined needle roller bearings

**Table 17** provides suitable tolerance classes for the housing bore and shaft for combined needle roller bearings with or without an inner ring.

In addition to their interference fit on the shaft and in the housing, the bearing rings should be located axially by a shaft shoulder or locating ring.

**Table 17**

**Shaft and housing tolerance classes for combined needle roller bearings**

Thrust part	Tolerance classes <sup>1)</sup>	
	Housing bore seat	Shaft seat (raceway and inner ring seat)
Angular contact ball bearing	M6	k5
Thrust ball bearing	K6 <sup>2)</sup>	k5
Cylindrical roller thrust bearing	K6 <sup>2)</sup>	k5

<sup>1)</sup> All ISO tolerance classes are valid with the envelope requirement (such as H7(Ⓔ)) in accordance with ISO 14405-1.

<sup>2)</sup> For stiff bearing arrangements, SKF recommends an M6(Ⓔ) housing bore tolerance class.

## 6 Needle roller bearings

### Mounting

Drawn cup and alignment needle roller bearings should be pressed into the housing bore using a mounting dolly (→ **fig. 44**). An O-ring provides a simple means of retaining the bearing on the mounting dolly. The stamped side face should abut the flange of the mounting dolly.

Special care should be taken to prevent the sleeve from skewing or tilting when it is being pressed into the housing. Otherwise the rollers and raceways could easily be damaged.

For grease lubricated bearings, the bearing should be lubricated prior to mounting.

### Paired mounting

If roller sets or bearings are to be mounted immediately adjacent to each other, the load should be shared equally by both roller sets or bearings. Therefore, the following need to be considered:

- Arrangements with just needle rollers should incorporate rollers of the same gauge.
- Needle roller and cage assemblies should incorporate rollers of the same gauge.
- Drawn cup needle roller bearings should have the same deviations from the nominal inside diameter  $F_w$ .

A delivery of needle rollers of the same nominal diameter may contain packages of one or more gauges. The gauge limits are also printed on the package.

For needle roller and cage assemblies the deviation from the nominal dimensions of the fitted needle rollers is printed on the package.

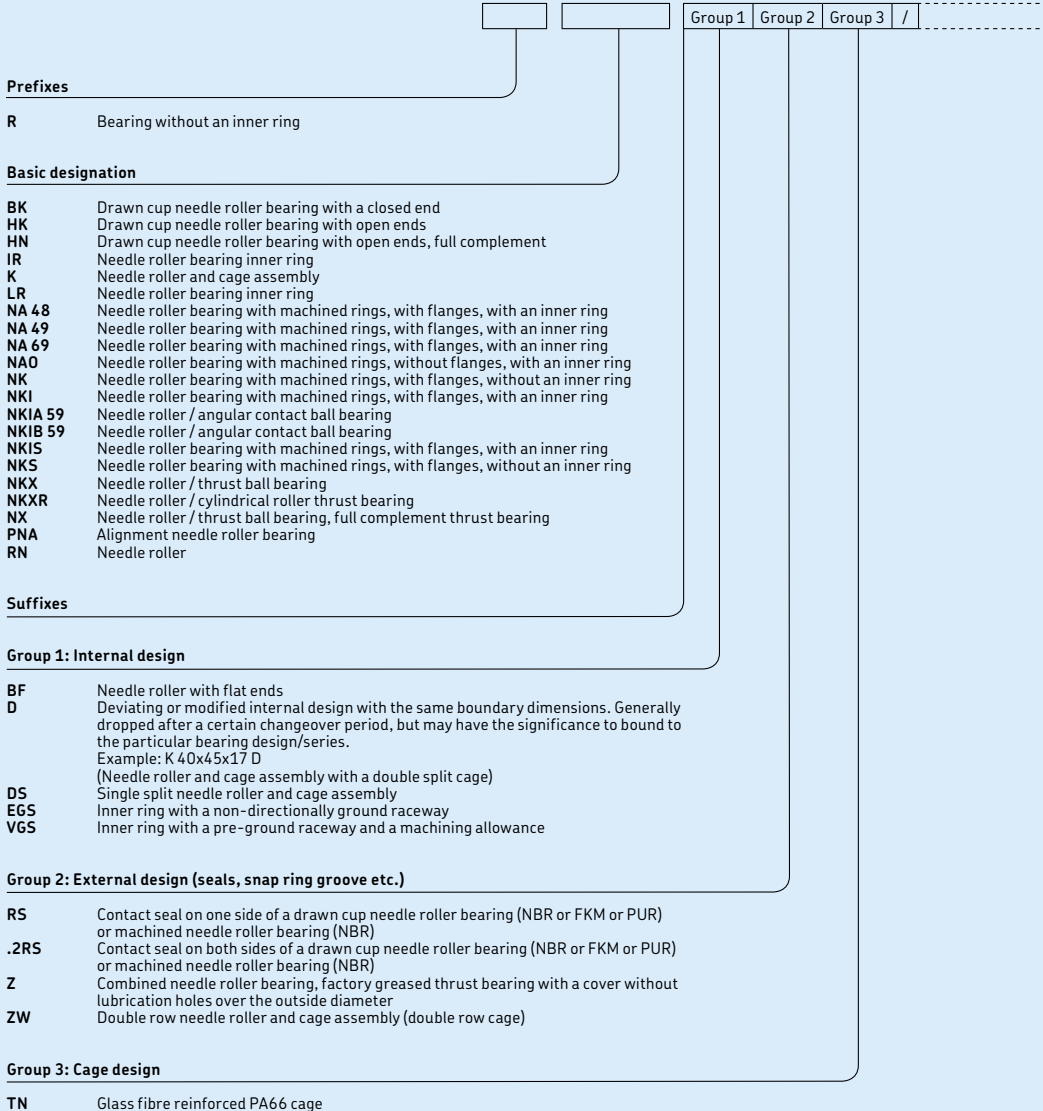

For additional information about gauges and inside diameter, refer to *Tolerances* (→ **page 700**).

Group 4					
4.1	4.2	4.3	4.4	4.5	4.6

**Group 4.6: Other variants**

**VG052** Single split PES (polyethersulfone) cage

**Group 4.5: Lubrication**

- AS..** Outer ring with lubrication hole(s), the number following indicates the number of holes
- ASR..** Outer ring with annular groove and lubrication hole(s), the number following indicates the number of holes
- IS..** Inner ring with lubrication hole(s), the number following indicates the number of holes
- ISR..** Inner ring with annular groove and lubrication hole(s), the number following indicates the number of holes
- SM..** Special grease, two numbers following identify the grease

**Group 4.4: Stabilization**

- S0** Bearing heat stabilized for operating temperatures  $\leq 150\text{ }^{\circ}\text{C}$  (300 °F)
- S1** Bearing heat stabilized for operating temperatures  $\leq 200\text{ }^{\circ}\text{C}$  (390 °F)
- S2** Bearing heat stabilized for operating temperatures  $\leq 250\text{ }^{\circ}\text{C}$  (480 °F)
- S3** Bearing heat stabilized for operating temperatures  $\leq 300\text{ }^{\circ}\text{C}$  (570 °F)

**Group 4.3: Bearing sets, matched bearings**

**..S** Matched bearings for an equal load distribution. The number preceding indicates the number of bearings, e.g. NK 50/25 TN/25

**Group 4.2: Accuracy, clearance, preload, quiet running**

- /SORT..** Tolerance grade of needle rollers of a needle roller and cage assembly, the numbers following identify the actual limits in  $\mu\text{m}$ , e.g. /SORT-2-4
- CN** Normal radial internal clearance; only used together with an additional letter that identifies a reduced or displaced clearance range
  - H** Reduced clearance range corresponding to the upper half of the actual clearance range
  - L** Reduced clearance range corresponding to the lower half of the actual clearance range
  - M** Reduced clearance range corresponding to the two middle quarters of the actual clearance range
  - P** Displaced clearance range comprising the upper half of the actual clearance range plus the lower half of the next larger clearance range
  - R** Normal clearance range in accordance with the withdrawn DIN 620-4:1982
 The above letters H, L, M and P are also used together with the clearance classes C2, C3, C4
- C2** Radial internal clearance smaller than Normal
- C3** Radial internal clearance greater than Normal
- C4** Radial internal clearance greater than C3
- G2** Needle roller in accordance with ISO 3096 Grade 2
- H..** Bearing without an inner ring and reduced inside diameter (under rollers) tolerance, the numbers following indicate the tolerance limits in  $\mu\text{m}$ , e.g. H+27+20
- M../M..** Diameter tolerance of needle rollers, e.g. M2/M4 indicates diameter tolerance  $-2$  to  $-4\text{ }\mu\text{m}$
- N/M..** Diameter tolerance of needle rollers, e.g. N/M2 indicates diameter tolerance 0 to  $-2\text{ }\mu\text{m}$
- P5** Dimensional and running accuracy to P5 tolerance class
- P6** Dimensional and running accuracy to P6 tolerance class
- P62** P6 + C2
- P63** P6 + C3
- P6CNR** P6 + CNR

## Designs and variants

Tapered roller bearings have tapered inner and outer ring raceways and tapered rollers. They are designed to accommodate combined loads, i.e. simultaneously acting radial and axial loads. The projection lines of the raceways meet at a common point on the bearing axis (→ **fig. 1**) to provide true rolling and low friction. The axial load carrying capacity of tapered roller bearings increases with increasing contact angle  $\alpha$ . The size of the angle is related to the calculation factor  $e$  (→ **product tables**): the larger the value of  $e$ , the larger the contact angle. A single row tapered roller bearing is typically adjusted against a second tapered roller bearing.

Single row tapered roller bearings are separable (→ **fig. 2**), i.e. the inner ring with roller and cage assembly (cone) can be mounted separately from the outer ring (cup).

The factors that influence SKF bearing performance and service life include but are not limited to the following:

- **roller end / flange contact area**

The geometry and surface finish of the roller ends and the area on the flange that makes contact with the roller ends (→ **fig. 3**) have been optimized to promote and maintain the formation of a lubricant film. This reduces friction and frictional heat as well as flange wear. The bearings can better maintain preload and run at reduced noise levels.

- **raceway profiles**

To extend service life under misalignment or heavy load conditions, SKF tapered roller bearings have either crowned raceways or a logarithmic profile to prevent stress peaks at the roller ends. The logarithmic profile is designed to optimize load distribution along the rollers.

- **consistency of profiles and roller size**

The rollers used in SKF tapered roller bearings are made to such close tolerances that they are virtually identical. These extremely close tolerances, together with the precision of the raceway profiles, provide optimal load distribution over the rollers to reduce noise and vibration levels and enable preload to be set more accurately.

**Running-in**

Tapered roller bearings typically have a running-in period. During the running-in period, a conventional design tapered roller bearing experiences a significant amount of friction, resulting in wear, which can be noticed as a temperature spike (→ **diagram 1**). With current SKF tapered roller bearing designs, friction, wear and frictional heat are significantly reduced, provided the bearings are mounted and lubricated correctly.

### Assortment

The assortment listed in this catalogue comprises popular sizes of metric single row tapered roller bearings in accordance with ISO 355 and inch bearings in accordance with ANSI/ABMA Standard 19.2. It includes:

- basic design bearings
- TQ-line bearings (designation suffix Q)
- bearings with a flanged outer ring
- matched bearings

Tapered roller bearings listed in this catalogue constitute the basic SKF assortment and are only part of the total assortment. For information about

- other sizes of single row tapered roller bearings, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings).
- double row and four-row tapered roller bearings, refer to the product information available online at [skf.com/bearings](http://skf.com/bearings).
- hub units based on tapered roller bearings for industrial, automotive, railway and off-highway applications, contact SKF.

### Basic design bearings

The design and internal geometry of SKF basic design tapered roller bearings (→ **fig. 4**) enable these bearings to provide long service life. The crowned profile of the raceways and optimized surface finish of the inner ring guide flange enables these bearings to run cooler and consume less lubricant than conventional design bearings.

### TQ-line bearings

TQ-line tapered roller bearings (→ **fig. 4**) are identified by the designation suffix Q and have operating characteristics that clearly set them apart from bearings made to conventional designs. The logarithmic contact profile provides optimum load distribution in the roller / raceway contact area to keep stress peaks within acceptable limits, even under slight misalignment. Like SKF Explorer bearings, the roller end / flange contact area of TQ-line tapered roller bearings is designed to reduce friction and wear at start-up. Normally the bearings do not need running-in procedures after installation. Bearings that are preloaded experience only a small, controlled loss of initial preload.

### Bearings with a QCL7C designation suffix

Bearings identified by the designation suffix QCL7C were originally designed for use as pinion bearings in the differential of industrial transmissions to provide a constant, accurate gear mesh. The bearings are characterized by their high degree of running accuracy and high preload capability. They have special friction characteristics and can be axially adjusted within narrow limits using the friction-torque method. Their internal design promotes the formation of a hydrodynamic oil film to substantially reduce friction and consequently operating temperature during the running-in period. When installed, lubricated and maintained properly, bearings with a designation suffix QCL7C retain their preload setting.

Fig. 4

### Application specific bearings

For applications where the bearings are subjected to unique operating conditions, SKF can customize TQ-line bearings (designation suffix Q) to meet the needs of that particular application.

For additional information about application specific tapered roller bearings, contact the SKF application engineering service.

### Bearings with a flanged outer ring

Certain sizes of SKF single row tapered roller bearings are also available with a flange on the outer ring (→ **fig. 5**). Bearings with a flanged outer ring are relatively easy to locate axially in the housing. The housing bore is also easier and more cost-effective to manufacture, as shoulders are not required.

Fig. 5

## 7 Tapered roller bearings

### Matched bearings

Matched bearings (→ **fig. 6**) can be supplied for bearing arrangements where the load carrying capacity of a single bearing is inadequate, or where the shaft has to be located axially in both directions with a specific axial clearance or preload. The bearings and spacer(s) are matched in production and delivered as a set. When mounted, the radial load is evenly distributed between the bearings.

Depending on the requirements, matched bearings can be supplied in face-to-face, back-to-back, or tandem arrangements (→ **fig. 7**). The bearing set is supplied complete, with the appropriate spacer ring(s).

The matched bearings listed in this catalogue constitute the basic SKF assortment. Other matched bearings can be supplied on request.

#### Matched bearings arranged face-to-face

Matched bearings arranged face-to-face (→ **fig. 7**) have load lines that converge toward the bearing axis. Therefore, the arrangement can accommodate a limited amount of misalignment. Axial loads in both directions can be accommodated, but only by one bearing in each direction.

The bearing set is supplied with an intermediate outer ring spacer.

#### Matched bearings arranged back-to-back

Matched bearings arranged back-to-back (→ **fig. 7**) have load lines that diverge toward

Fig. 6

the bearing axis to provide a relatively stiff bearing arrangement that can also accommodate tilting moments. Axial loads in both directions can be accommodated, but only by one bearing in each direction.

The bearing set is supplied with intermediate inner and outer ring spacers.

#### Matched bearings arranged in tandem

Matched bearings arranged in tandem (→ **fig. 7**) have load lines that are parallel. Radial and axial loads are shared equally by the bearings. This arrangement is used when the load carrying capacity of a single bearing is inadequate. However, matched bearings arranged in tandem can accommodate axial loads in one direction only. If axial loads act in

Fig. 7

Face-to-face arrangement

Back-to-back arrangement

Tandem arrangement

both directions, a third bearing, adjusted against the tandem pair, must be added.

The bearing set is supplied with intermediate inner and outer ring spacers.

### Cages

SKF tapered roller bearings are fitted with stamped steel cages as standard. Bearings with polymer cages are available on request (→ **table 1**).

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

### Performance classes

#### SKF Explorer bearings

In response to the ever-demanding performance requirements of modern machinery, SKF developed the SKF Explorer performance class of rolling bearings.

SKF Explorer tapered roller bearings realized this substantial improvement in performance by optimizing the internal geometry and surface finish of all contact surfaces, combining the extremely clean and homogenous steel with a unique heat treatment, optimizing the roller end / flange contact area and cage and improving the roller profile and the quality and dimensional consistency of the rollers.

These improvements provide the following benefits:

- higher load carrying capacity
- improved wear-resistance
- reduced noise and vibration levels
- less frictional heat
- significantly extended bearing service life

SKF Explorer bearings reduce environmental impact by enabling downsizing and reducing both lubricant and energy consumption. Just as importantly, SKF Explorer bearings can reduce the need for maintenance and contribute to increased productivity.

SKF Explorer bearings are shown with an asterisk in the product tables. The bearings retain the designation of earlier standard bearings. However, each bearing and its box are marked with the name "SKF Explorer".

Other standard SKF tapered roller bearings can be manufactured in the SKF Explorer performance class on request. These bearings are identified by the designation suffix PEX.

#### SKF Energy Efficient (E2) bearings

To meet the ever-increasing demand to reduce friction and energy consumption, SKF has developed the SKF Energy Efficient (E2) performance class for rolling bearings. SKF E2 tapered roller bearings are characterized by a frictional moment in the bearing that is at least 30% lower when compared to a same-sized standard SKF bearing.

The bearings realized this substantial reduction of the frictional moment mainly by optimizing the internal geometry, number of rollers, surface finish and redesigning the cage.

Reduced operating temperatures improve lubrication conditions and enable extended lubrication intervals or higher speeds. The lower mass of the roller and cage assembly and reduced inertial forces in the bearing reduce the risk of skidding and smearing. Typical applications include wind energy transmissions, railway transmissions, ship transmissions and other heavy industrial transmissions.

Typically, SKF E2 tapered roller bearings are available on request. For additional information, contact the SKF application engineering service.

## 7 Tapered roller bearings

### Calculating the axial load for bearings mounted singly or paired in tandem

When a radial load is applied to a single row tapered roller bearing, the load is transmitted from one raceway to the other at an angle to the bearing axis and an internal axial load is induced. This must be considered when calculating the equivalent bearing loads for bearing arrangements consisting of two single bearings and/or bearing pairs arranged in tandem.

The necessary equations are provided in **table 5** for various bearing arrangements and load cases. The equations are only valid if the bearings are adjusted against each other to practically zero clearance, but without any preload. In the arrangements shown, bearing A is subjected to a radial load  $F_{rA}$  and bearing B to a radial load  $F_{rB}$ . Both  $F_{rA}$  and  $F_{rB}$  are always considered positive, even when they act in a direction opposite to what is shown in the figures. The radial loads act at the pressure centres of the bearings ( $\rightarrow$  distance  $a$  in the product tables).

$K_a$  is the external axial force acting on the shaft or on the housing. Load cases 1c and 2c are also valid when  $K_a = 0$ . Values of the factor  $Y$  are listed in the product tables.

## 7 Tapered roller bearings

### Calculating the radial load acting on matched bearings

When matched tapered roller bearings, arranged face-to-face or back-to-back, are mounted together with a third bearing, the bearing arrangement is statically indeterminate. In these cases, the radial load  $F_r$  acting on the bearing pair must be calculated first.

#### Matched bearings arranged face-to-face

For matched bearings, where two bearings are arranged face-to-face (→ **fig. 8**), it can be assumed that the radial load acts at the geometric centre of the matched bearings, as the distance between the pressure centres of the two bearings is short when compared with the distance between the geometric centres of the set and the other bearing. In this case, it can be assumed that the bearing arrangement is statically determined.

#### Matched bearings arranged back-to-back

The distance  $a$  between the pressure centres of two matched bearings arranged back-to-back is significant when compared with the distance  $L$  between the geometric centres of the matched bearings and the other bearing (→ **fig. 9**). Therefore, it is necessary to calculate the magnitude of the load acting on the bearing pair and also the distance  $a_1$  at which the load acts. The magnitude of the radial load can be obtained using

$$F_r = \frac{L_1}{L - a_1} K_r$$

where

$F_r$  = radial load acting on a bearing pair [kN]

$K_r$  = radial force acting on the shaft [kN]

$L$  = distance between the geometric centres of the two bearing positions [mm]

$L_1$  = distance between the centre of bearing position I and the point of action of the force  $K_r$  [mm]

$a$  = distance between the bearing pressure centres [mm]

$a_1$  = distance between the geometric centre of the matched bearings, and the point of action of the radial load  $F_r$  [mm]

The distance  $a_1$  can be determined using **diagram 2**. The distance of the pressure centres  $a$  and the calculation factor  $Y_2$  are listed in the product tables.

### Temperature limits

The permissible operating temperature for tapered roller bearings can be limited by:

- the dimensional stability of the bearing rings and rollers
- the cage
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

#### Bearing rings and rollers

SKF tapered roller bearings undergo a special heat treatment. The bearings are heat stabilized up to:

- $D \leq 160 \text{ mm}$  →  $120 \text{ }^\circ\text{C}$  ( $250 \text{ }^\circ\text{F}$ )
- $D > 160 \text{ mm}$  →  $150 \text{ }^\circ\text{C}$  ( $300 \text{ }^\circ\text{F}$ )

#### Cages

Steel or PEEK cages can be used at the same operating temperatures as the bearing rings and rollers. For temperature limits of cages made of other polymer materials, refer to *Cage materials* (→ page 152).

#### Lubricants

Temperature limits for SKF greases are provided under *Lubrication* (→ page 239). When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ page 244).

### Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ page 117).

### Design of bearing arrangements

Single row tapered roller bearings must either be used with a second bearing or as a matched pair (→ fig. 10). The bearings must be adjusted against each other until the requisite clearance or preload is obtained (→ *Bearing preload*, page 214). To maximize bearing performance and operational reliability, the appropriate clearance or preload must be selected and then applied during the mounting process. When the operating clearance in a bearing arrangement is too large, the load carrying capacity of both bearings cannot be fully utilized. Excessive preload increases friction, which increases the amount of frictional heat and reduces bearing service life.

#### Fits for inch bearings

In contrast to metric bearings, which are machined to a minus tolerance, inch bearings are machined to a plus tolerance (→ table 9, page 143). Therefore, the deviations for shaft and housing diameters for metric bearings are not applicable. Tables 6 and 7 (→ pages 818 and 819) provide the shaft and housing fits for inch tapered roller bearings that are valid for Normal tolerance bearings in typical applications:

- **Table 6:** Shaft diameter deviations for inch bearings
- **Table 7:** Housing bore diameter deviations for inch bearings

## Fits for matched bearings

The axial internal clearance of matched bearings arranged face-to-face or back-to-back (→ table 4, page 810) provides an appropriate operating clearance when the bearings are mounted on shafts machined to:

- $d \leq 140 \text{ mm}$  → m5<sup>Ⓔ</sup>
- $140 \text{ mm} < d \leq 200 \text{ mm}$  → n6<sup>Ⓔ</sup>
- $d > 200 \text{ mm}$  → p6<sup>Ⓔ</sup>

These shaft seat tolerance classes are recommended for normal to heavy rotating loads on the inner ring. If tighter fits are selected, be sure that the bearings are not “clamped” and that they are able to rotate freely. For additional information about shaft tolerances, contact the SKF application engineering service.

For stationary outer ring loads, the recommended housing bore tolerance class is J6<sup>Ⓔ</sup> or H7<sup>Ⓔ</sup>.

7

## Adjustment procedure

When adjusting tapered roller bearings against each other, the bearings must be rotated so that the rollers assume their correct position, i.e. the large end face of the rollers must be in contact with the guide flange.

# Bearing designations

### Metric bearings

The designations of metric tapered roller bearings that are in accordance with ISO standards follow one of the following principles:

- The series designations in accordance with ISO 355 consist of a digit and two letters. The digit represents the contact angle. The two letters represent the diameter and width series, respectively. This is followed by a three-digit bore diameter  $d$  [mm]. The basic designations of SKF tapered roller bearings start with the letter T, e.g. T2ED 045.
- Designations established prior to 1977 are based on the system shown under *Basic designations*, e.g. 32206 (→ **diagram 2, page 43**).
- Metric bearings with the designation prefix J follow the ABMA designation system which is used for inch bearings (→ ANSI/ABMA Standard 19.2).

### Inch bearings

Inch tapered roller bearing designations are in accordance with ANSI/ABMA 19.2.

All inch bearings within a series use the same roller and cage assembly but the inner and outer rings can have different sizes and designs.

Any inner ring with roller and cage assembly (cone) can be assembled with any outer ring (cup) belonging to the same bearing series. For this reason, the cup and cone have individual designations and can be supplied separately (→ **fig. 11**). The designations of cups and cones as well as the series consist of a three- to six-digit number which may be prefixed to characterize a bearing series from extra-light to extra-heavy.

The complete bearing designation consists of the cone designation followed by that of the cup. The two designations are separated by an oblique stroke. To shorten the complete bearing designations, abbreviations are used (→ **table 8**).

### Prefixes

- E2.** SKF Energy Efficient bearing
- J** Metric bearing following the ABMA designation system (ANSI/ABMA Standard 19.2)
- T** Metric bearing in accordance with ISO 355

### Basic designation

Refer to *Bearing designations* (→ page 820)

### Suffixes

#### Group 1: Internal design

- B** Steep contact angle

#### Group 2: External design (seals, snap ring groove etc.)

- R** Flanged outer ring
- T..** A number immediately following the T identifies the total width of matched bearings, arranged back-to-back or in tandem.
- X** Boundary dimensions changed to conform to ISO

#### Group 3: Cage design

- J..** Stamped steel cage, roller centred. A number following the J indicates a different cage design.
- TN9** Glass fibre reinforced PA66 cage, roller centred
- TNH** Glass fibre reinforced PEEK cage, roller centred

#### Group 4.1: Materials, heat treatment

- HA1** Case-hardened inner and outer rings
- HA3** Case-hardened inner ring
- HN1** Inner and outer rings with special surface heat treatment
- HN3** Inner ring with special surface heat treatment

Group 4					
4.1	4.2	4.3	4.4	4.5	4.6

**Group 4.6: Other variants**

- CL7A** Pinion bearing, superseded by CL7C
- CL7C** High-performance design
- CLN** Reduced tolerances for ring widths and total (abutment) width in accordance with ISO tolerance class 6X
- PEX** SKF Explorer bearing on customer request
- Q** Optimized contact geometry and surface finish
- V001** CL7C and /2
- VA321** Optimized internal design
- VA606** Crowned raceway on the outer ring, logarithmic profile on the inner ring and special heat treatment
- VA607** Same as VA606, but other outside diameter tolerance
- VC027** Modified internal geometry for increased permissible misalignment
- VC068** Increased running accuracy and special heat treatment
- VQ051** Modified internal geometry for increased permissible misalignment
- VQ267** Reduced inner ring width tolerance to  $\pm 0,025$  mm
- VQ495** CL7C with reduced or shifted tolerance range for the outside diameter
- VQ506** Reduced inner ring width tolerance
- VQ507** CL7C with reduced or shifted tolerance range for the outside diameter
- VQ523** CL7C with reduced inner ring width tolerance and reduced or shifted tolerance range for the outside diameter
- VQ601** Accuracy to ABMA tolerance class 0 for inch bearings
- VB022** Chamfer dimension of large outer ring side face 0,3 mm
- VB026** Chamfer dimension of large inner ring side face 3 mm
- VB061** Chamfer dimension of large inner ring side face 8 mm
- VB134** Chamfer dimension of large inner ring side face 1 mm
- VB406** Chamfer dimension of large inner and outer ring side faces 3 mm
- VB481** Chamfer dimension of large inner ring side face 8,5 mm
- VE174** One locating slot in the large side face of the outer ring, improved running accuracy

**Group 4.5: Lubrication**

**Group 4.4: Stabilization**

**Group 4.3: Bearing sets, matched bearings**

- DB..** Two bearings matched for mounting back-to-back. A number immediately following the DB identifies the design of the spacer rings.
- DF..** Two bearings matched for mounting face-to-face. A number immediately following the DF identifies the design of the spacer ring.
- DT..** Two bearings matched for mounting in tandem. A number immediately following the DT identifies the design of the spacer rings.

**Group 4.2: Accuracy, clearance, preload, quiet running**

- /1**
- /-1**
- to
- /-3**
- /4**
- C...** Special clearance. The two- or three-digit number immediately following the C is the mean axial internal clearance in  $\mu\text{m}$ . The range remains the same as specified in **table 4** ( $\rightarrow$  **page 810**).
- CL0** Accuracy to ABMA tolerance class 0 for inch bearings
- CL00** Accuracy to ABMA tolerance class 00 for inch bearings
- P5** Dimensional and running accuracy to P5 tolerance class
- U..** U combined with a one- or two-digit number identifies reduced total width tolerance, e.g.:  
 U2 ...  $+0,05/0$  mm  
 U4 ...  $+0,10/0$  mm
- W** Modified ring width tolerance to  $+0,05/0$  mm

## Designs and variants

Spherical roller bearings have two rows of rollers, a common sphered outer ring raceway and two inner ring raceways inclined at an angle to the bearing axis (→ **fig. 1**). The centre point of the sphere in the outer ring raceway is at the bearing axis. Therefore, the bearings are self-aligning (→ **fig. 2**) and insensitive to misalignment of the shaft relative to the housing, which can be caused, for example, by shaft deflection. Spherical roller bearings are designed to accommodate heavy radial loads, as well as heavy axial loads in both directions.

### Factors that influence SKF spherical roller bearing performance

Bearing performance is not only determined by load or speed ratings. There are a number of other factors that contribute to bearing performance. To a large extent, performance is influenced by the geometry of the rollers, raceways and cages, the heat treatment, as well as the surface finish of all contact surfaces. Main factors which influence SKF spherical roller bearing performance include, but are not limited to:

- Symmetrical rollers**  
 Symmetrical rollers self-adjust (→ fig. 3), providing optimal load distribution along the roller length. This keeps stresses low under all load conditions and extends bearing service life.
- Roller tolerances**  
 The rollers in an SKF spherical roller bearing are manufactured to extremely tight tolerances for dimension and form. Each roller is virtually identical in size and shape to the other rollers in the set. This optimizes load distribution over the rollers to maximize bearing service life.
- Special roller profile**  
 The roller profile determines the stress distribution in the roller/raceway contact area. The special profile distributes loads more evenly along the rollers and prevents stress

Fig. 5

peaks at the roller ends to extend bearing service life (→ fig. 4).

- Self-guiding rollers and a floating guide ring between the two rows of rollers**  
 Self-guiding rollers reduce friction and frictional heat (→ fig. 5). A floating guide ring guides unloaded rollers so that they enter the load zone in the optimal position.
- Metal cages**  
 All SKF spherical roller bearings contain strong metal cages. This enables them to tolerate high temperatures and all lubricants.

## 8 Spherical roller bearings

### Assortment

The assortment of SKF spherical roller bearings is the widest on the market and includes standard bearings and application specific bearings. Almost all SKF spherical roller bearings are available with either a cylindrical or tapered bore. Depending on the bearing series, the tapered bore has a taper of either 1:12 (designation suffix K) or 1:30 (designation suffix K30).

The assortment of standard bearings includes:

- basic design bearings
- sealed bearings
- bearings for vibratory applications
- SKF Energy Efficient (E2) bearings

Spherical roller bearings listed in this catalogue constitute the basic SKF assortment and are only part of the total assortment. For applications where the bearings are subjected to unique operating conditions, SKF can customize bearings to meet the needs of that particular application. For example, bearings for:

- printing presses, paper mills or coaters in high precision execution
- very arduous operating conditions, e. g. continuous casters
- high temperature applications
- mounting with loose fit on roll necks
- railway vehicles

For additional information about application specific spherical roller bearings, contact the SKF application engineering service.

### Basic design bearings

Depending on their series and size, standard SKF spherical roller bearings are manufactured to one of following basic designs (→ fig. 6):

- CC design bearings have two stamped window-type steel cages, an inner ring without flanges and a floating guide ring centred on the inner ring. The CC design is indicated by the designation suffix C or CC. Large CC design bearings with the designation suffix EC or ECC have an optimized internal design for increased load carrying capacity.
- CA design bearings have a machined double prong-type brass cage, an inner ring with a retaining flange on both sides and a floating guide ring centred on the inner ring. The flanges on the inner ring are designed to keep the rollers in place when swivelling the bearing during installation or maintenance. The flanges are not designed to guide the rollers or accommodate any axial load. The CA design is indicated by the designation suffix CA. Large CA design bearings with the designation suffix ECA have an optimized internal design for increased load carrying capacity.

- E design bearings have two stamped window-type steel cages, an inner ring without flanges and a floating guide ring centred on the inner ring ( $d \leq 65$  mm) or on the cages ( $d > 65$  mm). They have an annular groove and three lubrication holes in the outer ring. E design bearings are indicated by the designation suffix E. All E design bearings have an optimized internal design for increased load carrying capacity.

#### Annular groove and lubrication holes

SKF spherical roller bearings are available with an annular groove and three lubrication holes in the outer ring (designation suffix W33) or three lubrication holes in the outer ring (designation suffix W20) (→ **fig. 7**). SKF E design bearings (→ **fig. 6**) and SKF Energy Efficient (E2) bearings have an annular groove and three lubrication holes as standard and therefore, the W33 designation suffix is not necessary.

#### Cages

Cages in SKF spherical roller bearings are an integral part of the bearing internal design. Depending on their internal design, series and size, SKF spherical roller bearings are fitted with one of the cages shown in **fig. 6**. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

Fig. 7

### Sealing solutions

With the exception of bearings designated with a BS2- prefix, the boundary dimensions of sealed spherical roller bearings are in accordance with ISO 15. Bearings with a BS2- prefix, for example BS2-2214-2CS, are based on 222 E or 223 E series bearings, but are slightly wider to accommodate the seals.

Sealed spherical roller bearings have the same features and internal design as basic design spherical roller bearings and are available with a cylindrical bore as standard. Some sizes are also available with a tapered bore or can be supplied with a tapered bore on request.

Sealed spherical roller bearings have a contact seal reinforced with a sheet steel insert, fitted on both sides. They can also be supplied with a seal on only one side. The bearings can be fitted with seals made of one of the following materials:

- NBR (designation suffix CS)
- HNBR (designation suffix CS5)
- FKM (designation suffix CS2)

The seals are fitted in a recess on the outer ring and seal against the inner ring. On larger bearings, the seals are fixed by a retaining ring (→ fig. 8).

Sealed spherical roller bearings are supplied lubricated and should not be washed. For many application conditions, the bearings do not require relubrication and can be consid-

ered relubrication-free (→ *Relubrication of sealed bearings*).

SKF does not recommend heating sealed spherical roller bearings above 80 °C (175 °F) during the mounting process. However, if higher temperatures are necessary, make sure that the temperature does not exceed the permissible temperature of either the seal or grease, whichever is lowest.

#### WARNING

Seals made of FKM (fluoro rubber) exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions under *Seal materials* (→ page 155).

### Greases for sealed bearings

Sealed spherical roller bearings are filled as standard with SKF LGEP 2 grease. Bearings filled with SKF LGHB 2 grease can be supplied on request. Technical specification of both greases are listed in **table 1**.

For additional information about greases, refer to *Lubrication* (→ **page 239**).

### Relubrication of sealed bearings

Sealed spherical roller bearings are designed to operate relubrication-free. For bearings lubricated with the standard grease LGEP 2 (designation suffix VT143), the relubrication-free operating conditions can be identified using **diagram 1**. The diagram is valid for bearings in light to normal load applications ( $P \leq 0,1 C$ ) on a horizontal shaft and a load ratio  $F_a/F_r \leq e$ . For other operating conditions, the grease life can be estimated by multiplying

the relubrication interval for open bearings (→ *Relubrication*, **page 252**) by a factor of 2,7.

In applications that have a life requirement outside the green area of **diagram 1** (→ **page 885**), the bearings may require relubrication. If relubrication is required and the bearing has a polymer band covering the lubrication holes in the outer ring, remove the band prior to mounting (→ **fig. 9**).

A suitable grease quantity to relubricate sealed bearings can be obtained using

$$G_p = 0,0015 D B$$

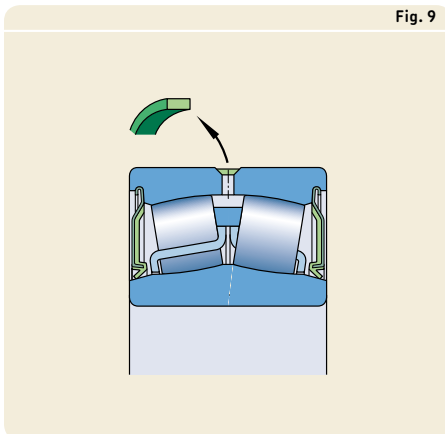

where

$G_p$  = grease quantity [g]

$D$  = bearing outside diameter [mm]

$B$  = bearing width [mm]

The grease should be applied slowly through the lubrication holes in the outer ring while the bearing is rotating, if possible, to avoid damaging the seals. SKF recommends relubricating with the same grease as the initial fill.

### Bearings for vibratory applications

For vibratory applications, SKF supplies spherical roller bearings with a cylindrical or tapered bore and surface-hardened stamped steel cages (series designations 223../VA405). These bearings have the same dimensions and performance characteristics as basic design bearings, but have C4 radial internal clearance as standard.

Bearings for vibratory applications are also available with a PTFE coated cylindrical bore (designation suffix VA406). These bearings are manufactured to VA405 specifications, with the exception of the bore. VA406 bearings are intended for the non-locating bearing position in vibratory applications with outer ring rotation. The PTFE coating prevents fretting corrosion between the shaft and the bearing bore. Therefore, shafts do not require special heat treatments or coatings.

All bearings are equipped with an annular groove and three lubrication holes in the outer ring.

Depending on their size, SKF spherical roller bearings for vibratory applications are manufactured to one of following designs (→ fig. 10):

- E/VA405 spherical roller bearings have two surface-hardened stamped window-type steel cages, an inner ring without flanges and a floating guide ring centred on the inner ring or on the cages.
- EJA/VA405 and CCJA/W33VA405 spherical roller bearings have two surface-hardened stamped window-type steel cages, an inner ring without flanges and a floating guide ring centred on the outer ring raceway.

#### WARNING

PTFE coatings exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions under *Seal materials* (→ page 155).

## 8 Spherical roller bearings

### Acceleration

Vibratory applications, such as vibrating screens or exciters, induce accelerations of rollers and cages in the bearings. This puts extra demands on the bearing design. SKF spherical roller bearings for vibratory applications can withstand considerably faster accelerations than corresponding standard bearings. The permissible acceleration depends on the lubricant and the mode of acceleration.

- Mode 1  
The bearing is subjected to a rotating outer ring load in combination with a rotating acceleration field, or an internally induced angular acceleration field due to rapid speed variations. These accelerations cause the unloaded rollers to generate cyclic loads on the cages.
- Mode 2  
The bearing is subjected to impact loads, which generate a linear acceleration in a constant radial direction, causing the unloaded rollers to “hammer” the cage pockets.

Typical examples for mode 1 are vibrating screens (→ **fig. 11**), planetary gears and general arrangements subjected to rapid starts or rapid speed variations. A typical example for mode 2 is the acceleration generated when rail wheels roll over rail joints (→ **fig. 12**). Road rollers, where the roller is vibrating against a

relatively hard surface, are subjected to a combination of mode 1 and 2 acceleration.

Values for the permissible acceleration are listed in the product tables and are valid for oil lubricated bearings. The values are expressed in multiples of  $g$ , where  $g$  is the acceleration of gravity ( $g = 9,81 \text{ m/s}^2$ ).

### System solutions for vibrating screens

In addition to single bearings for vibrating screens, SKF has developed fault detection and bearing systems that can improve performance, reduce maintenance and monitor machine condition in vibratory equipment. For additional information about the SKF Copperhead system solution for vibrating screens, contact the SKF application engineering service.

## Performance classes

### SKF Explorer bearings

In response to the ever-demanding performance requirements of modern machinery, SKF developed the SKF Explorer performance class of rolling bearings.

SKF Explorer spherical roller bearings realized this substantial improvement in performance by optimizing the internal geometry and surface finish of all contact surfaces, combining the extremely clean and homogenous steel with a unique heat treatment, improving the cage, roller profile and the geometry of the raceways.

These improvements provide the following benefits:

- higher dynamic load carrying capacity compared to conventional design bearings
- improved wear-resistance
- reduced noise and vibration levels
- less frictional heat
- significantly extended bearing service life

SKF Explorer bearings reduce environmental impact by enabling downsizing and reducing both lubricant and energy consumption. Just as importantly, SKF Explorer bearings can reduce the need for maintenance and contribute to increased productivity.

SKF Explorer bearings are shown with an asterisk in the product tables. The bearings retain the designation of earlier standard bearings. However, each bearing and its box are marked with the name “SKF EXPLORER”.

### SKF Energy Efficient (E2) bearings

To meet the ever-increasing demand to reduce friction and energy consumption, SKF has developed the SKF Energy Efficient (E2) performance class of rolling bearings. SKF E2 spherical roller bearings are characterized by a frictional moment in the bearing that is at least 30% lower when compared to a same-sized SKF Explorer bearing.

Reduced operating temperatures improve lubrication conditions and enable extended lubrication intervals or higher speeds.

The enhanced performance characteristics require the following conditions:

- speed  $n > 500$  r/min
- operating temperature  $\leq 110$  °C (230 °F)
- load  $P \leq 0,067$  C
- lubrication and relubrication with SKF LESA 2 grease only (→ **table 2**).

For loads  $P > 0,067$  C, SKF Explorer bearings are more beneficial.

### Temperature limits

The permissible operating temperature for spherical roller bearings can be limited by:

- the dimensional stability of the bearing rings
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

#### Bearing rings

SKF spherical roller bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 200 °C (390 °F) for 2 500 h, or for brief periods at even higher temperatures.

#### Seals

The permissible operating temperature for seals depends on the material:

- NBR seals:  
–40 to +90 °C (–40 to +195 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- HNBR seals:  
–40 to +150 °C (–40 to +300 °F)
- FKM seals:  
–30 to +200 °C (–20 to +390 °F)

#### Lubricants

Temperature limits for the greases used in SKF spherical roller bearings are provided in **table 1** (→ **page 885**) for sealed bearings and in **table 2** (→ **page 889**) for SKF E2 bearings. Temperature limits for other SKF greases are provided under *Lubrication* (→ **page 239**).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

### Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**). If no reference speed is listed in the product tables, the limiting speed is the permissible speed.

To achieve their special performance characteristics, SKF E2 spherical roller bearings must operate at speeds above the recommended minimum speed of 500 r/min.

## Design of bearing arrangements

### Free space on both sides of the bearing

To prevent interference between rotating and stationary components, the abutment diameter on the shaft should be  $< d_2$  and in the housing  $> D_1$  (→ **fig. 14**). Values for  $d_2$  and  $D_1$  are listed in the product tables.

The necessary width of the free space  $C_a$  depends on:

- the actual misalignment
- the possible protrusion of the cage from the side face of the bearing for some bearing sizes
- lubrication requirements

That requisite free space should be at least 20 times the minimum value of the radial internal clearance in the unmounted bearing (→ **table 4, page 892** or **table 5, page 893**).

For additional information, contact the SKF application engineering service.

## 8 Spherical roller bearings

### Abutments for sealed bearings

The diameter of the shaft abutment should not exceed  $d_{a\max}$  (→ **product tables**) at least for the 1 to 2 mm closest to the bearing, to prevent interference with the seal (→ **fig. 15**). If the bearings are to be located axially on the shaft by a lock nut, SKF recommends using a KMFE lock nut (→ **fig. 16**) or a spacer ring (→ **fig. 17**) between the bearing and the lock washer to prevent interference with the seal.

### Bearings on sleeves

Spherical roller bearings with a tapered bore can be mounted on plain or stepped shafts with an adapter sleeve (→ **fig. 18**) or on stepped shafts with a withdrawal sleeve (→ **fig. 19**). Adapter sleeves are supplied complete with a locking device. For additional information about sleeves, refer to *Bearing accessories* (→ **page 1269**).

When using sealed spherical roller bearings on an adapter sleeve, the locking device must not interfere with the seal. To avoid this, use an appropriate SKF adapter sleeve assembly for sealed bearings (→ **fig. 20**), as listed in the product tables (→ **page 954**). Alternatively, a spacer ring can be inserted between the bearing and the lock washer.

### Appropriate bearing housings

The combination of a spherical roller bearing, appropriate sleeve, where needed, and an appropriate SKF bearing housing provides a cost-effective, interchangeable and reliable solution that fulfils the demand for easy maintenance. Appropriate SKF housings are available in a variety of designs and sizes for a wide range of applications. The designs include:

- split and non-split plummer (pillow) block housings
- flanged housings
- take-up housings

Additional information about SKF bearing housings is available online at [skf.com/housings](http://skf.com/housings).

## 8 Spherical roller bearings

### Mounting

Due to the design of spherical roller bearings, the rings and roller complement may be displaced axially from the normal position during handling. Therefore, SKF recommends mounting spherical roller bearings when the shaft or housing is in the horizontal position. Also, whenever possible, rotate the inner or outer ring to align the rollers during mounting.

If spherical roller bearings are mounted when the shaft or housing is in the vertical position, the roller complement, together with the inner or outer ring will move downward until there is no more clearance. Then, when the bearing rings expand or contract as a result of an interference fit, a preload is likely to result. To prevent this preload condition from occurring, rotate the inner or outer ring during installation. If this is not feasible, use a bearing handling tool or other device to keep the bearing components arranged centrally.

### Mounting bearings with a tapered bore

Bearings with a tapered bore are always mounted with an interference fit. To obtain the proper degree of interference, one of the following methods can be used:

- 1 measuring the clearance reduction
- 2 measuring the lock nut tightening angle
- 3 measuring the axial drive-up
- 4 applying the SKF Drive-up Method
- 5 measuring the inner ring expansion (SensorMount)

For additional information about these mounting methods, refer to *Mounting, dismounting and bearing care* (→ **page 271**), or the *SKF bearing maintenance handbook*.

For bearings with  $d > 100$  mm, SKF recommends using the SKF Drive-up Method. This is a fast, reliable and safe method to achieve the appropriate interference fit. Additional information is available online at [skf.com/drive-up](https://skf.com/drive-up).

Recommended values to apply methods 1 to 3 are listed in **table 7**.

**NOTE:** Applying the recommended values prevents the inner ring from creeping, but does not ensure correct radial internal clearance in operation. Additional influences from the bearing housing fit and temperature differences between the inner and outer rings must be considered carefully when selecting the bearing radial internal clearance class. For additional information, contact the SKF application engineering service.

<sup>2)</sup> The listed values are to be used as guideline values only, as it is difficult to establish an exact starting position. Also, the axial drive-up s differs slightly between the different bearings series.

**Group 4.6: Other variants**

- VA405** Bearing for vibratory applications, surface-hardened stamped steel cages
- VA406** Same as VA405, but PTFE coated cylindrical inner ring bore
- VE552(E)** Outer ring with three equally spaced threaded holes in one side face to accommodate lifting tackle. The E indicates that appropriate eye bolts are supplied with the bearing.
- VE553(E)** Same as VE552(E), but threaded holes in both side faces
- VG114** Surface-hardened stamped steel cages
- VQ424** Running accuracy better than C08

**Group 4.5: Lubrication**

- GEM9** Filled to 70 – 100% with SKF LGHB 2 grease
- VT143** Filled to 25 – 45% with SKF LGEP 2 grease
- VT143B** Filled to 45 – 60% with SKF LGEP 2 grease
- VT143C** Filled to 70 – 100% with SKF LGEP 2 grease
- W64** Solid Oil
- W** Without annular groove and lubrication holes in the outer ring
- W20** Three lubrication holes in the outer ring
- W26** Six lubrication holes in the inner ring
- W33** Annular groove and three lubrication holes in the outer ring
- W33X** Annular groove and six lubrication holes in the outer ring
- W77** Plugged W33 lubrication holes
- W513** W26 + W33

**Group 4.4: Stabilization**

**Group 4.3: Bearing sets, matched bearings**

**Group 4.2: Accuracy, clearance, preload, quiet running**

- C08** Running accuracy to P5 tolerance class
- C083** C08 + C3
- C084** C08 + C4
- C2** Radial internal clearance smaller than Normal
- C3** Radial internal clearance greater than Normal
- C4** Radial internal clearance greater than C3
- C5** Radial internal clearance greater than C4
- P5** Dimensional and running accuracy to P5 tolerance class
- P6** Dimensional and running accuracy to P6 tolerance class
- P62** P6 + C2

**Group 4.1: Materials, heat treatment**

- 235220** Case-hardened inner ring with a helical groove in the bore
- HA3** Case-hardened inner ring

## Designs and variants

CARB toroidal roller bearings (→ **fig. 1**) combine the self-aligning capability of spherical roller bearings with the axial displacement ability of cylindrical roller bearings (→ **fig. 2**). CARB bearings can also have the compact cross section and high load carrying capacity normally associated with needle roller bearings.

CARB bearings are intended exclusively as non-locating bearings. They can simplify locating/non-locating bearing arrangements because thermal elongation of the shaft can be accommodated within the bearing virtually without friction. Bearing systems consisting of a spherical roller bearing in the locating position and a CARB bearing in the non-locating position (→ **fig. 6, page 162**) provide a space- and weight-saving bearing system with a low cost of ownership. CARB bearings can reduce noise and vibration levels, for example, in paper machines and fans.

CARB bearings are single row bearings with long, slightly barrel-shaped symmetrical rollers. The outer ring has a torus-shaped raceway with a profile radius extending beyond the centre of the bearing. The inner ring raceway is shaped accordingly. The rollers of CARB

Fig. 1

bearings are self-guiding, i.e. they always adopt the position where the load is favourably distributed over the roller length, irrespective of whether the bearing rings are misaligned or axially displaced. The ability to distribute loads favourably keeps the friction and frictional heat at low levels. Lower operating temperatures extend the service life of the lubricant and the bearing.

### Factors that influence CARB bearing performance

Bearing performance is not only determined by load or speed ratings. There are a number of other factors that contribute to bearing performance. To a large extent, performance is influenced by the geometry of the rollers, raceways and cages, the heat treatment, as well as the surface finish of all contact surfaces. Main factors which influence CARB bearing performance include, but are not limited to:

- **Symmetrical rollers**

Symmetrical rollers self-adjust, providing optimal load distribution along the roller length. This keeps stresses low under all load conditions and extends bearing service life.

- **Roller tolerances**

The rollers in a CARB bearing are manufactured to extremely tight tolerances for dimension and form. Each roller is virtually identical in size and shape to the other rollers in the set. This optimizes load distribution over the rollers to maximize bearing service life.

- **Special roller profile**

The roller profile determines the stress distribution in the roller/raceway contact area. The special profile distributes loads more evenly along the rollers and prevents stress peaks at the roller ends to extend bearing service life (→ fig. 3).

- **Self-guiding rollers**

Self-guiding rollers keep friction and frictional heat at low levels (→ fig. 4).

### Assortment

The assortment of CARB toroidal roller bearings matches the assortment of spherical roller bearings. The assortment also includes bearings with a low cross-sectional height to meet the requirements for minimum radial space. The majority of CARB bearings are available with either a cylindrical or tapered bore. Depending on the bearing series, the tapered bore has a taper of either 1:12 (designation suffix K) or 1:30 (designation suffix K30).

The assortment of standard bearings includes:

- basic design bearings
- sealed bearings
- bearings for vibratory applications

CARB bearings listed in this catalogue constitute the basic SKF assortment and are only part of the total assortment. For applications where the bearings are subjected to unique operating conditions, SKF can customize bearings to meet the needs of that particular application. For example, bearings for:

- paper mills or coaters in high precision execution
- very arduous operating conditions, e.g. continuous casters
- high temperature applications

For additional information about application specific CARB bearings, contact the SKF application engineering service.

Fig. 5

### Basic design bearings

Depending on their series and size, standard CARB toroidal roller bearings are manufactured to one of the following basic designs (→ fig. 5):

- bearings with a roller centred cage  
(no designation suffix, designation suffix TN9 or designation suffix M)
- bearings with an inner ring centred cage  
(designation suffix MB)
- full complement bearings  
(designation suffix V)

The load carrying capacity of full complement CARB bearings is considerably higher than that of same-sized bearings with a cage.

## 9 CARB toroidal roller bearings

### Sealing solutions

The assortment of sealed bearings (→ **fig. 6**) consists of small and medium-size full complement bearings with a cylindrical bore. These bearings, which are typically used in applications where there are slow speeds and very heavy loads, can accommodate inner or outer ring rotation. The seals are designed for long service life and make the bearings virtually relubrication-free.

Sealed bearings have a double lip contact HNBR seal on one or both sides (designation suffix CS5 or 2CS5). The seals are reinforced with a sheet steel insert. They are fitted in a recess on the outer ring and seal against the inner ring raceway.

### Greases for sealed bearings

Sealed CARB bearings are filled with a high-quality grease (→ **table 1**) that has good corrosion inhibiting properties. Sealed bearings with non-standard grease fills can be supplied on request.

## Bearings for vibratory applications

For vibratory applications, SKF supplies CARB bearings with a cylindrical or tapered bore and a surface-hardened stamped steel cage (series designation C 23../C4VG114). These bearings have the same dimensions and product data as bearings in the C 23 series.

CARB bearings can be mounted with an interference fit on the shaft and in the housing because axial displacement is accommodated within the bearing. This avoids fretting corrosion, which otherwise can occur, if a radial bearing is mounted with a loose fit.

For additional information about CARB bearings in the C 23../C4VG114 series, contact the SKF application engineering service.

## Cages

Cages in CARB toroidal roller bearings are an integral part of the bearing internal design. Depending on their series and size, CARB bearings are fitted with one of the following cages:

- a glass fibre reinforced PA46 cage, window-type, roller centred (designation suffix TN9)
- a stamped steel cage, window-type, roller centred (no designation suffix)
- a machined brass cage, window-type, roller centred (designation suffix M)
- a machined brass cage, prong-type, inner ring centred (designation suffix MB)

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

## Performance classes

### SKF Explorer bearings

In response to the ever-demanding performance requirements of modern machinery, SKF developed the SKF Explorer performance class of rolling bearings.

All CARB bearings are manufactured to the SKF Explorer performance class and are shown with an asterisk in the product tables. Each box is marked with the name “SKF EXPLORER”.

<b>Misalignment</b>	0,5° For misalignment greater than 0,5°, contact the SKF application engineering service.
(→ <b>fig. 7, page 968</b> )	Misalignment greater than 0,5° increases friction and reduces bearing service life. The ability to accommodate misalignment when the bearing is stationary is also limited. For CARB bearings with a machined brass cage centred on the inner ring (designation suffix MB), misalignment should never exceed 0,5°.
<b>Friction, starting torque, power loss</b>	Frictional moment, starting torque and power loss can be calculated as specified under <i>Friction</i> (→ <b>page 97</b> ), or using the tools available online at <a href="http://skf.com/bearingcalculator">skf.com/bearingcalculator</a> .

... the outer ring of 6 to 8% of the bearing width reduces the operating clearance to approximately the same value as same-sized spherical roller bearings.

Misalignment displaces the rollers axially, causing them to approach the side faces of the bearing rings. Therefore, possible axial displacement is reduced (→ *Axial displacement*, page 968).

## 9 CARB toroidal roller bearings

### Axial displacement

CARB toroidal roller bearings can accommodate axial displacement of the shaft relative to the housing within the bearing. The permissible axial displacement from the normal position of one bearing ring relative to the other is limited by two criteria:

- **Displacement of the roller set**  
Misalignment as well as axial displacement influences the axial position of the rollers in a CARB bearing (→ **fig. 7**). The rollers should not protrude from the side face of a bearing ring (→ **fig. 8**) or make contact with a retaining ring (→ **fig. 9**) or seal. To accommodate the displacement of the roller and cage assembly, free space must be provided on both sides of the bearing (→ *Free space on both sides of the bearing*, page 974).
- **Sufficient radial internal clearance**  
CARB bearings should always operate with radial internal clearance. The axial position of the rollers influences the radial internal clearance. The typical clearance window for a CARB bearing is illustrated in **diagram 1**. The diagram also illustrates calculation examples 2 and 3 (→ **page 970**).

The permissible axial displacement is obtained from the smaller of these two limitations.

Fig. 7

Fig. 8

Fig. 9

Diagram 1

The clearance window for a C 3052 CARB bearing with a maximum operating clearance of 0,150 mm

Calculating the permissible axial displacement

**Limited by the displacement of the roller set**

When the bearing rings are not misaligned, the axial displacement is limited by the values  $s_1$  or  $s_2$  (→ **figs. 8 and 9, page 968**).

When the bearing rings are misaligned, the axial displacement values  $s_1$  or  $s_2$  must be reduced:

$$s_{rol} = s_1 - k_1 B \alpha \quad \text{or} \quad s_{rol} = s_2 - k_1 B \alpha$$

**Calculation example 1**

What is the maximum axial displacement the roller set permits for a C 3052 bearing when the bearing rings are misaligned by  $\alpha = 0,3^\circ$ ?

$$s_{rol} = s_1 - k_1 B \alpha$$

$$s_{rol} = 19,3 - 0,122 \times 104 \times 0,3 = 15,5 \text{ mm}$$

**Limited by the reduction of internal clearance**

The axial displacement for a maximum clearance reduction can be estimated using:

$$s_{cle} = \sqrt{\frac{B C_{red}}{k_2}}$$

The clearance reduction caused by a certain axial displacement can be estimated using:

$$C_{red} = \frac{k_2 s_{cle}^2}{B}$$

**Calculation example 2**

What is the maximum axial displacement for a C 3052 bearing if a maximum internal clearance reduction of 0,15 mm is permitted?

$$s_{cle} = \sqrt{\frac{B C_{red}}{k_2}}$$

$$s_{cle} = \sqrt{\frac{104 \times 0,15}{0,096}} = 12,7 \text{ mm}$$

See also **diagram 1** (→ **page 969**).

**Calculation example 3**

What internal clearance reduction does an axial displacement from the central position of 6,5 mm cause in a C 3052 bearing?

$$C_{red} = \frac{k_2 s_{cle}^2}{B}$$

$$C_{red} = \frac{0,096 \times 6,5^2}{104} = 0,039 \text{ mm}$$

See also **diagram 1** (→ **page 969**).

$s_{cle}$	= maximum axial displacement from a centred position, corresponding to a certain radial clearance reduction [mm]
$s_{rol}$	= maximum axial displacement limited by the roller set, including misalignment effect [mm]

 $B = 104 \text{ mm}$ 
 $s_1 = 19,3 \text{ mm}$

 $k_2 = 0,096$ 
**Offset mounting**

Bearing rings are usually mounted so that they are not displaced relative to each other. However, if considerable thermal changes in shaft length can be expected, the inner ring can be mounted offset, relative to the outer ring, up to the axial displacement limit  $s_1$  or  $s_2$  (→ **fig. 9, page 968**) in the direction opposite to the expected shaft elongation (→ **fig. 10**) or contraction. Offsetting one ring relative to the other, extends the permissible axial displacement. This advantage is used, for example, in the bearing arrangements of drying cylinders in paper machines.

For additional information (→ page 86)	When starting up at low temperatures or when the lubricant is highly viscous, even greater minimum loads than $F_{rm} = 0,007 C_0$ and $0,01 C_0$ , respectively, may be required. ## Temperature limits

The permissible operating temperature for CARB bearings can be limited by:

- the dimensional stability of the bearing rings
- the cage
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing rings

CARB bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 200 °C (390 °F) for 2 500 h, or for brief periods at even higher temperatures.

### Cages

Steel or brass cages can be used at the same operating temperatures as the bearing rings. For temperature limits of polymer cages, refer to *Cage materials* (→ **page 152**).

### Seals

The permissible operating temperature for HNBR seals is -40 to +150 °C (-40 to +300 °F).

### Lubricants

Temperature limits for the grease used in sealed CARB toroidal roller bearings are provided in **table 1** (→ **page 962**). Temperature limits for other SKF greases are provided under *Lubrication* (→ **page 239**).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

## Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**). If no reference speed is listed in the product tables, the limiting speed is the permissible speed.

## Design of bearing arrangements

### Free space on both sides of the bearing

To enable axial displacement of the shaft relative to the housing, free space must be provided on both sides of the bearing as indicated in **fig. 11**. The value for the width of this free space is based on:

- the value  $C_a$  (→ **product tables**)
- the expected axial displacement of the bearing rings from the central position during operation
- the displacement of the rings caused by misalignment

For additional information, refer to *Axial displacement* (→ **page 968**).

Fig. 12

### Bearings on sleeves

CARB bearings with a tapered bore can be mounted on plain or stepped shafts with an adapter sleeve (→ **fig. 12**) or on stepped shafts with a withdrawal sleeve (→ **fig. 13**). Adapter sleeves are supplied complete with a locking device. For additional information about sleeves, refer to *Bearing accessories* (→ **page 1269**).

When using CARB bearings on an adapter sleeve, appropriate SKF adapter sleeve assemblies must be used to prevent the locking device from interfering with the cage (→ **product tables, page 1000**). Check axial displacement carefully, as it could be that  $s_1$  (→ **product tables, page 980**) cannot be fully realized.

## 9 CARB toroidal roller bearings

### Appropriate bearing housings

The combination of a CARB bearing, appropriate sleeve, where needed, and an appropriate SKF bearing housing provides a cost-effective, interchangeable and reliable solution for the non-locating bearing position that fulfils the demand for easy maintenance. SKF standard housings are available for almost all CARB bearings in the 0, 1, 2 and 3 diameter series.

Two arrangements are possible when using standard housings, without requiring special considerations:

- CARB bearings with a tapered bore on an adapter sleeve and a plain shaft
- CARB bearings with a cylindrical bore on a stepped shaft

Additional information about SKF bearing housings is available online at [skf.com/housings](http://skf.com/housings).

### Mounting

Due to the design of CARB toroidal roller bearings, the rings and roller complement may be displaced axially from their normal position during handling. Therefore, SKF recommends mounting CARB bearings when the shaft or housing is in the horizontal position. Also, whenever possible, rotate the inner or outer ring to align the rollers during mounting.

If CARB bearings are mounted when the shaft or housing is in the vertical position, the roller complement, together with the inner or outer ring will move downward until there is no more clearance. Then, when the bearing rings expand or contract as a result of an interference fit, a preload is likely to result. To prevent this preload condition from occurring, rotate the inner or outer ring during installation. If this is not feasible, use a bearing handling tool or other device to keep the bearing components arranged centrally.

### Mounting bearings with a tapered bore

Bearings with a tapered bore are always mounted with an interference fit. To obtain the proper degree of interference, one of the following methods can be used:

- 1 measuring the clearance reduction
- 2 measuring the lock nut tightening angle
- 3 measuring the axial drive-up
- 4 applying the SKF Drive-up Method
- 5 measuring the inner ring expansion (SensorMount)

For additional information about these mounting methods, refer to *Mounting, dismounting and bearing care* (→ **page 271**), or the *SKF bearing maintenance handbook*.

For bearings with  $d > 100$  mm, SKF recommends using the SKF Drive-up Method. This is a fast, reliable and safe method to achieve the appropriate interference fit. Additional information is available online at [skf.com/drive-up](http://skf.com/drive-up).

Recommended values to apply methods 1 to 3 are listed in **table 5**.

**NOTE:** Applying the recommended values prevents the inner ring from creeping, but does not ensure correct radial internal clearance in operation. Additional influences from the bearing housing fit and temperature differences between the inner and outer rings must be considered carefully when selecting the bearing radial internal clearance class. For additional information, contact the SKF application engineering service.

Valid only for solid steel shafts and general applications.

<sup>1)</sup> Not valid for the SKF Drive-up Method.

<sup>2)</sup> The listed values are to be used as guideline values only, as it is difficult to establish an exact starting position. Also, the axial drive-up s differs slightly between the different bearings series.

## Designs and variants

SKF thrust ball bearings are manufactured as single direction or double direction thrust ball bearings. They are designed to accommodate axial loads only and must not be subjected to any radial load.

SKF thrust ball bearings are separable, i.e. the shaft washer, housing washer(s), ball and cage assembly(s) can be mounted separately.

Shaft washers have a ground bore to enable an interference fit. The bore of the housing washer is turned and always larger than the shaft washer bore.

### Single direction thrust ball bearings

SKF single direction thrust ball bearings consist of a shaft washer, a housing washer and a ball and cage assembly (→ **fig. 1**). As their name implies, single direction thrust ball bearings can accommodate axial loads and locate a shaft axially, in one direction only.

### Double direction thrust ball bearings

SKF double direction thrust ball bearings consist of one shaft washer, two housing washers and two ball and cage assemblies (→ **fig. 2**). The housing washers and ball and cage assemblies of double direction bearings are identical to those used in single direction bearings. Double direction thrust ball bearings can accommodate axial loads and locate a shaft axially, in both directions.

### Cages

Depending on their series and size, SKF thrust ball bearings are fitted with one of the cages shown in **table 1**.

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

### Bearings with sphered housing washers

To accommodate initial misalignment between the shaft and housing, SKF supplies both single and double direction thrust ball bearings with sphered seat surfaces on the housing washers (→ **fig. 3**). They can be used together with a sphered seat washer adjacent to the housing washer (→ **figs. 4 and 5**) or adjacent to a machine component manufactured with a sphered surface.

Appropriate sphered seat washers must be ordered separately (→ **product tables**). Depending on the bearing series, they have the basic designation U 2, U 3 or U 4 followed by a two-digit number, which identifies the size (e.g. sphered seat washer U 320 for bearing 53320).

### Temperature limits

The permissible operating temperature for thrust ball bearings can be limited by:

- the dimensional stability of the bearing washers and balls
- the cage
- the seat washer(s)
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

#### Bearing washers and balls

The washers and balls of SKF thrust ball bearings undergo a special heat treatment. Depending on their size they are heat stabilized up to:

- 125 °C (260 °F) when  $d \leq 300$  mm
- 150 °C (300 °F) when  $d > 300$  mm

#### Cages

Steel and brass cages can be used at the same operating temperatures as the bearing washers and balls.

#### Seat washers

Seat washers are made of steel and can be used at the same operating temperatures as the bearing washers and balls.

#### Lubricants

Temperature limits for SKF greases are provided under *Lubrication* (→ **page 239**). When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

### Permissible speed

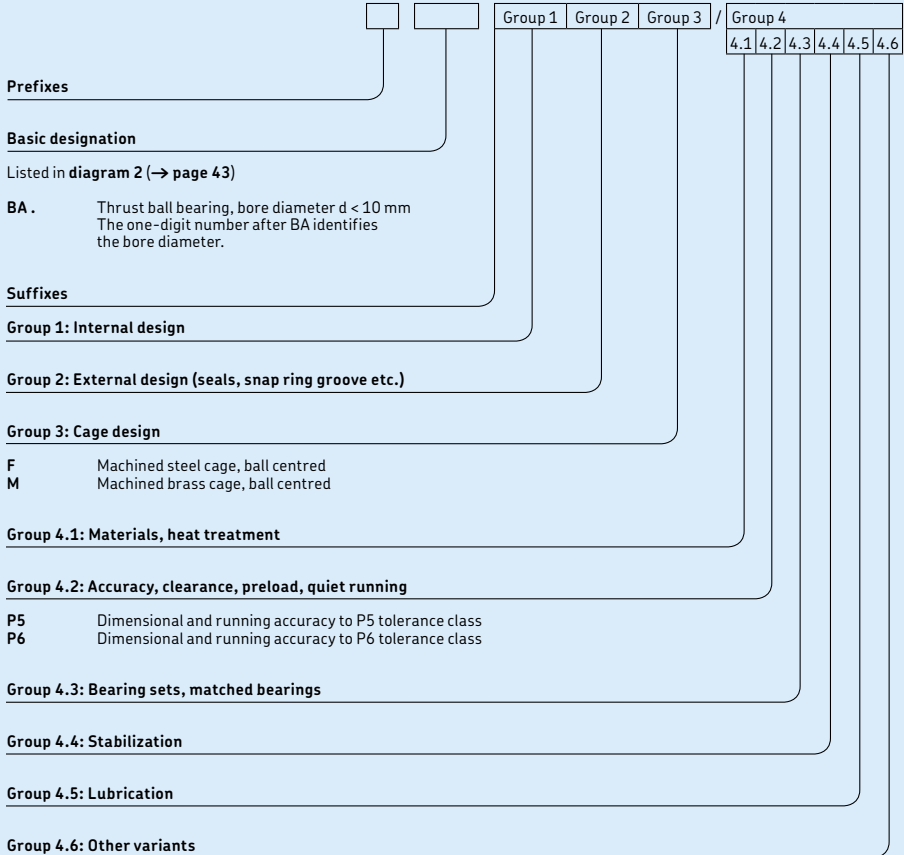

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**).

### Mounting

When installing a single direction thrust ball bearing it is important to differentiate between the shaft washer and the housing washer. The bore of the shaft washer is ground and always smaller than the bore of the housing washer. The shaft washer should always be placed against a shaft step or fixed shaft component.

## 11 Cylindrical roller thrust bearings

### Designs and variants

SKF cylindrical roller thrust bearings are designed to accommodate heavy axial loads and shock loads. They must not be subjected to any radial load. The ends of the rollers are relieved slightly to modify the line contact between the raceways and rollers. This prevents stress peaks at the roller ends to extend bearing service life.

Cylindrical roller thrust bearings are very stiff and require little axial space. They are separable, that means that shaft washer, housing washer, and cylindrical roller and cage thrust assembly can be mounted separately.

Cylindrical roller thrust bearings are manufactured with one or two rows of rollers (→ **fig. 1**). Bearings in the 811 and 812 series are mainly used in applications where thrust ball bearings do not have sufficient load carrying capacity.

#### Single direction cylindrical roller thrust bearings

As standard, cylindrical roller thrust bearings are available as single direction bearings (→ **fig. 1**) and can accommodate axial loads in one direction only.

#### Double direction cylindrical roller thrust bearings

Double direction cylindrical roller thrust bearings can accommodate axial loads in both

directions. They can be created by combining two cylindrical roller and cage thrust assemblies and two bearing washers with an intermediate washer. Depending on the design, an intermediate washer can be shaft or housing centred (→ **fig. 2**).

Intermediate washers must have the same surface finish and hardness as bearing washers. SKF does not supply intermediate washers, but provides material specifications and dimensional data on request

For additional information, refer to *Design of bearing arrangements* (→ **page 1046**).

### Components

SKF can supply the components of cylindrical roller thrust bearings (→ **fig. 3**) separately. The components are listed in the product tables and include:

- cylindrical roller and cage thrust assemblies (prefix K)
- shaft washers (prefix WS)
- housing washers (prefix GS)

Single components might be required for applications where:

- The faces of adjacent machine components can serve as raceways and bearing arrangements with a low axial section height are required.
- Other combinations of cylindrical roller and cage thrust assemblies and washers are required, for example with two shaft or housing washers.

### Bearing washers

SKF supplies bearing washers in different designs and series. Bearing washers are required in cases where adjacent machine components cannot serve as raceways. Appropriate washers are listed in the product tables.

#### Shaft and housing washers

Shaft washers (prefix WS) and housing washers (prefix GS) are made of hardened carbon chromium bearing steel. The raceway surfaces are precision ground. Shaft washers have a ground bore while housing washers have a ground outside surface. Therefore, SKF rec-

ommends using these washers in high-speed applications where accurate centring of the bearing washers is required.

#### LS series universal washers

LS series universal washers can be used as both shaft or housing washers for bearings in the 811 series. These washers are used for applications where accurate centring of the bearing washers is not necessary or where slow speeds are involved.

For additional information about these washers, refer to *Needle roller thrust bearings* (→ **page 1057**).

### Cages

Depending on their series and size, SKF cylindrical roller thrust bearings are fitted with one of the cages shown in **table 1**.

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

## Temperature limits

The permissible operating temperature for cylindrical roller thrust bearings can be limited by:

- the dimensional stability of the bearing washers and rollers
- the cage
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing washers and rollers

SKF cylindrical roller thrust bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 120 °C (250 °F).

### Cages

Brass cages can be used at the same operating temperatures as the bearing washers and rollers. For temperature limits of polymer cages, refer to *Cage materials* (→ **page 152**).

### Lubricants

Temperature limits for SKF greases are provided under *Lubrication* (→ **page 239**). When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

## Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**).

## 11 Cylindrical roller thrust bearings

### Design of bearing arrangements

#### Abutment dimensions

The support surfaces in housings and on shafts should be at right angles to the shaft axis and provide uninterrupted support over the entire washer face. The abutment diameter on the shaft should be  $\geq d_{a \min}$  and in the housing  $\leq D_{a \max}$  (→ **fig. 4**). Values for  $d_{a \min}$  and  $D_{a \max}$  are listed in the product tables.

To provide satisfactory radial guidance for the individual thrust bearing components, suitable tolerance classes for shafts and housings are listed in **table 4**. A radial gap between the shaft and washer bore is required for housing centred washers. Shaft centred washers require a radial gap between the washer and housing bore.

Cylindrical roller and cage thrust assemblies are generally centred radially by the shaft, to reduce the circumferential speed at which the cage slides against the guiding surface. This is particularly important for higher speed applications. The guiding surface should be ground.

#### Raceways on shafts and in housings

If the load carrying capacity of a cylindrical roller and cage thrust assembly is to be fully exploited, the raceways on the shaft or in the housing should have the same hardness, surface finish and axial run-out as a bearing washer.

The dimensions  $E_a$  and  $E_b$  (→ **product tables**) take the possible displacement of the roller set into consideration and should be applied when designing raceways on shafts and in housings.

For additional information, refer to *Raceways on shafts and in housings* (→ **page 210**).

## Designs and variants

SKF needle roller thrust bearings are fitted with a form-stable cage to reliably retain and guide a large number of needle rollers. The very small diameter deviation of the rollers within one assembly enables these bearings to accommodate heavy axial loads and shock loads. The ends of the rollers are relieved slightly to modify the line contact between the raceways and rollers. This prevents stress peaks at the roller ends to extend bearing service life.

Needle roller thrust bearings provide a high degree of stiffness within a minimum axial space. In applications where the faces of adjacent machine components can serve as raceways, needle roller thrust bearings take up no more space than a conventional thrust washer. SKF supplies needle roller thrust bearings in two designs (→ fig. 1):

- needle roller and cage thrust assemblies, AXK series
- needle roller thrust bearings with a centring flange, AXW series (→ fig. 3)

In applications where adjacent components cannot serve as raceways, the assemblies can be combined with bearing washers in different series (→ *Bearing washers*, page 1060).

## Needle roller and cage thrust assemblies

SKF needle roller and cage thrust assemblies in the AXK series (→ fig. 1) are available for shaft diameters ranging from 4 to 160 mm. They can be combined with washers in the LS, AS, GS 811 or WS 811 series (→ *Bearing washers*, page 1060) in applications where adjacent components cannot serve as raceways. These thrust assemblies can accommodate axial loads in one direction only.

## Double direction bearings

Double direction needle roller thrust bearings can accommodate axial loads in both directions. They can be created by combining two needle roller and cage thrust assemblies and two bearing washers with an intermediate washer. Depending on the design, an intermediate washer can be shaft or housing centred (→ fig. 2).

Fig. 1

Intermediate washers must have the same hardness and surface finish as bearing washers. SKF does not supply intermediate washers, but provides material specifications and dimensional data on request.

For additional information, refer to *Design of bearing arrangements* (→ **page 1068**).

### Needle roller thrust bearings with a centring flange

SKF needle roller thrust bearings in the AXW series (→ **fig. 3**) consist of a needle roller and cage thrust assembly and a thrust washer with a centring flange. The flange facilitates mounting and accurately centres the housing washer radially (→ **figs. 4 and 5, page 1060**). These thrust assemblies, which accommodate axial loads in one direction only, are available for shaft diameters ranging from 10 to 50 mm.

## 12 Needle roller thrust bearings

### Combined needle roller bearing arrangements

To accommodate combined radial and axial loads, needle roller thrust bearings in the AXW series can be combined with the following radial needle roller bearings:

- drawn cup needle roller bearings with a closed end or with open ends (→ **fig. 4**)
- needle roller bearings with machined rings (→ **fig. 5**)

These arrangements provide a cost-effective and compact solution for combined loads.

### Bearing washers

SKF supplies bearing washers in different designs and series. The following series can be combined with needle roller thrust bearings:

- LS series universal washers
- AS series thin universal washers
- 811 series shaft and housing washers

Bearing washers are required in applications where adjacent machine components cannot serve as raceways.

Appropriate washers are listed in the product tables and must be ordered separately, due to the number of possible combinations.

Fig. 4

Fig. 5

### LS series universal washers

LS series universal washers (→ **fig. 6**) are made of hardened carbon chromium bearing steel. They can be used as shaft or housing washers for needle roller thrust bearings in the AXK series and as housing washers for bearings in the AXW series. LS series washers are available for shaft diameters ranging from 6 to 160 mm. The raceway surface is ground, while all other surfaces are turned. These washers are used for applications where accurate centring of the washers is not necessary or where slow speeds are involved. The washer face opposite the side with the chamfers is the raceway surface and should face the rollers.

Fig. 6

### AS series thin universal washers

AS series thin universal washers (→ **fig. 7**) are 1 mm thick, made of spring steel and hardened. They can be used as shaft or housing washers for needle roller thrust bearings in the AXK series and as housing washers for bearings in the AXW series. AS series washers are available for shaft diameters ranging from 4 to 160 mm. Both faces are polished and can be used as raceways. If adjacent machine components are not hardened, but have adequate stiffness and the running accuracy requirements are moderate, AS series thin universal washers can be used to provide a cost-effective bearing solution.

Fig. 7

### 811 series shaft and housing washers

Shaft and housing washers are used primarily with cylindrical roller and cage thrust assemblies. However, 811 series shaft washers (prefix WS) and housing washers (prefix GS) can also be combined with needle roller and cage thrust assemblies. These washers can be used in high-speed applications where accurate centring of the bearing washers is required.

For additional information about these washers, refer to *Cylindrical roller thrust bearings* (→ **page 1037**).

## 12 Needle roller thrust bearings

### Cages

Depending on their series and size, SKF needle roller thrust bearings are fitted with one of the cages shown in **table 1**. Bearings in the AXW series are fitted exclusively with steel cages.

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

## Temperature limits

The permissible operating temperature for needle roller thrust bearings can be limited by:

- the dimensional stability of the bearing washers and rollers
- the cage
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing washers and rollers

SKF needle roller thrust bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 120 °C (250 °F).

### Cages

Steel cages can be used at the same operating temperatures as the bearing washers and rollers. For temperature limits of polymer cages, refer to *Cage materials* (→ **page 152**).

### Lubricants

Temperature limits for SKF greases are provided under *Lubrication* (→ **page 239**). When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

## Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ **page 117**).

## Design of bearing arrangements

### Abutment dimensions

The support surfaces on shafts and in housings should be at right angles to the shaft or housing axis and should provide uninterrupted support over the entire washer face. The abutment diameter on the shaft should be  $\leq E_a$  and in the housing  $\geq E_b$ . Values for  $E_a$  and  $E_b$  ( $\rightarrow$  **product tables**) take the movement and position of the roller set into consideration.

To provide satisfactory radial guidance for the individual thrust bearing components, suitable tolerance classes for shafts and housings are listed in **table 4**. Radial space between the shaft and washer bore is required for housing centred washers. Shaft centred washers require radial space between the washer and housing bore.

Needle roller and cage thrust assemblies in the AXW series are generally combined with drawn cup needle roller bearings ( $\rightarrow$  **fig. 4, page 1060**) or needle roller bearings with machined rings ( $\rightarrow$  **fig. 5, page 1060**). The same housing tolerance must be selected for the centring flange as for the radial bearing.

Needle roller and cage thrust assemblies are generally shaft centred, to reduce the circumferential speed at which the cage slides against the guiding surface. This is particularly important for higher speed applications. The guiding surface should be ground.

### Raceways on shafts and in housings

If the load carrying capacity of a needle roller and cage thrust assembly is to be fully exploited, the raceways on the shaft or in the housing should have the same hardness, surface finish and axial run-out as a bearing washer.

The dimensions  $E_a$  and  $E_b$  ( $\rightarrow$  **product tables**) take displacement of the roller set into consideration and should be applied when designing raceways on shafts and in housings.

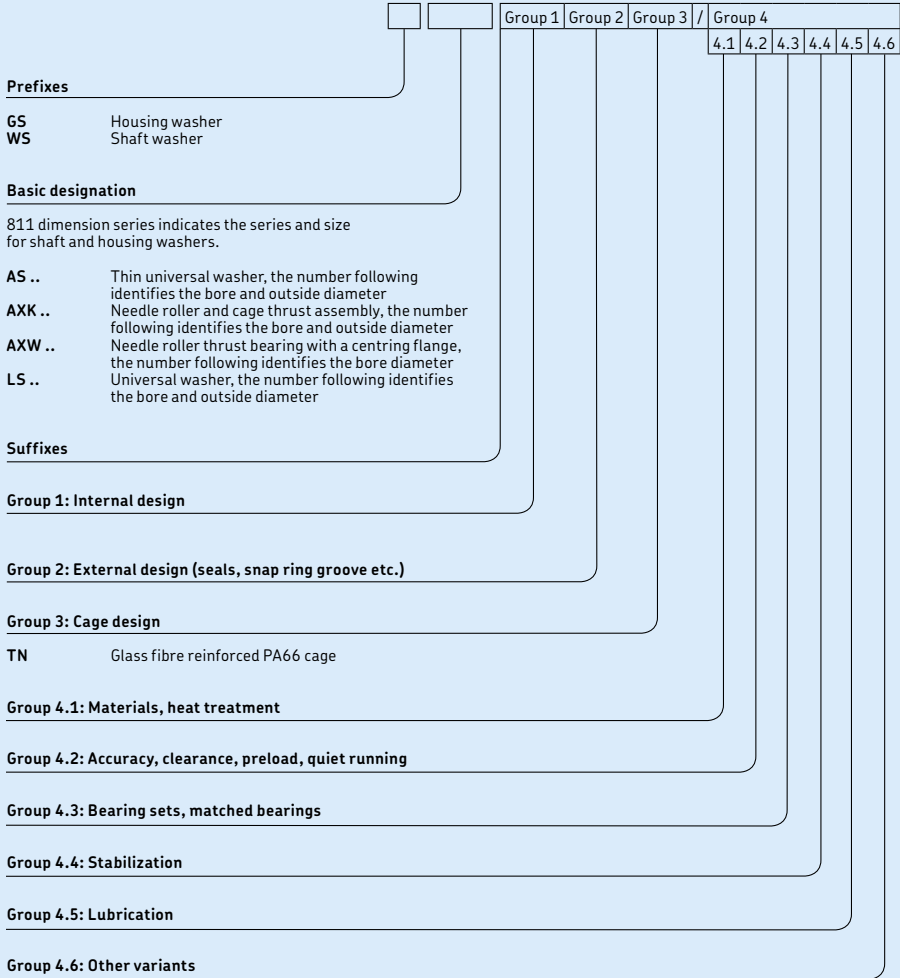

For additional information, refer to *Raceways on shafts and in housings* ( $\rightarrow$  **page 210**).

## 13 Spherical roller thrust bearings

### Designs

SKF spherical roller thrust bearings have specially designed raceways and accommodate a large number of asymmetrical rollers. The rollers have an optimum conformity with the washer raceways to optimize load distribution along the roller length. Therefore, they can accommodate relatively high speeds, heavy axial loads in one direction and heavy radial loads. The load is transmitted between the raceways at an angle to the bearing axis (→ **fig. 1**). Spherical roller thrust bearings are self-aligning and can accommodate misalignment of the shaft relative to the housing, which can be caused, for example, by shaft deflection.

### Basic design bearings

Depending on their series and size, SKF spherical roller thrust bearings are manufactured to two basic designs: bearings with no designation suffix and E design bearings.

Bearings with no designation suffix (e.g. 29272) are fitted with a machined prong-type brass cage as standard (→ **fig. 2**). The cage is guided by a sleeve held in the shaft washer bore. The shaft washer, cage and rollers form a non-separable unit.

Bearings with an E designation suffix have larger rollers and an optimized internal design for increased load carrying capacity. E design bearings up to size 68 are fitted with a stamped window-type steel cage (→ **fig. 3**), which forms a non-separable unit with the shaft washer and rollers.

E design bearings from size 72 and larger are fitted with a machined prong-type cage. This type of cage is guided by a sleeve held in the shaft washer bore. The shaft washer, cage and rollers form a non-separable unit.

## Cages

Cages in SKF spherical roller thrust bearings are an integral part of the bearing internal design. All SKF spherical roller thrust bearings contain a strong metal cage. This enables them to tolerate high temperatures and all lubricants.

For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

Fig. 3

## Performance classes

### SKF Explorer bearings

In response to the ever-demanding performance requirements of modern machinery, SKF developed the SKF Explorer performance class of rolling bearings.

SKF Explorer spherical roller thrust bearings realized this substantial improvement in performance by optimizing the internal geometry and surface finish of all contact surfaces, combining the extremely clean and homogeneous steel with a unique heat treatment, improving the cage, roller profile and the geometry of the raceways.

These improvements provide the following benefits:

- higher dynamic load carrying capacity compared to conventional design bearings
- improved wear-resistance
- reduced noise and vibration levels
- less frictional heat
- significantly extended bearing service life

SKF Explorer bearings reduce environmental impact by enabling downsizing and reducing both lubricant and energy consumption. Just as importantly, SKF Explorer bearings can reduce the need for maintenance and contribute to increased productivity.

SKF Explorer bearings are shown with an asterisk in the product tables. The bearings retain the designation of earlier standard bearings. However, each bearing and its box are marked with the name "SKF EXPLORER".

## Bearing data

<b>Dimension standards</b>	Boundary dimensions: ISO 104
<b>Tolerances</b>	Normal Total height H: <ul style="list-style-type: none"> <li>• for basic design bearings tolerance at least 50% tighter than ISO standard</li> <li>• for SKF Explorer bearings tolerance 75% tighter than ISO standard</li> </ul>
For additional information (→ <b>page 132</b> )	Values: ISO 199 (→ <b>table 10, page 144</b> )
<b>Misalignment</b>	The permissible misalignment is reduced as the load increases. Guideline values for misalignment and rotating shaft washer with respect to the housing washer: <b>table 1</b> . Whether these values can be fully exploited depends on the design of the bearing arrangement, the external sealing design, etc. When designing bearing arrangements with rotating housing washer in combination with misalignment or when the shaft wobbles in relation to the housing, contact the SKF application engineering service.
<b>Friction, starting torque, power loss</b>	Frictional moment, starting torque and power loss can be calculated as specified under <i>Friction</i> (→ <b>page 97</b> ), or using the tools available online at <a href="http://skf.com/bearingcalculator">skf.com/bearingcalculator</a> . For temperature and/or cooling requirement calculations in large bearings ( $d_m > 400 \text{ mm}$ ) <sup>1)</sup> , vertical shaft arrangements and fully submerged conditions, contact the SKF application engineering service.
<b>Defect frequencies</b>	Defect frequencies can be calculated using the tools available online at .

## Loads

### Minimum load

$$F_{am} = C_r F_r + A \left( \frac{n}{1\,000} \right)^2 + 20 F_{lub}$$

$$v n \geq 2\,000 \rightarrow F_{lub} = \frac{10^{-10} f_0 (v n)^{2/3} [0,5 (d + D)]^3}{d}$$

$$v n < 2\,000 \rightarrow F_{lub} = \frac{160 \times 10^{-10} f_0 [0,5 (d + D)]^3}{d}$$

The weight of the components supported by the bearing, together with external forces, generally exceed the requisite minimum load. If this is not the case, the bearing must be subjected to an additional axial load.

However, the requisite minimum load can be neglected for bearings operating at relatively slow speeds, depending on the outside diameter (→ **diagram 1, page 1084**).

**Example:**

For additional information (→ **page 86**)

A 29444 E bearing is to operate at 90 r/min, from **diagram 1** with  $D = 420$  mm the two lines converge below the blue line. Therefore, the minimum load requirement can be ignored.

### Equivalent dynamic bearing load

$F_r \leq 0,55 F_a$  and:

- if run-out in the bearing arrangement does not affect the load distribution in the spherical roller thrust bearing  
→  $P = 0,88 (F_a + X F_r)$
- if run-out in the bearing arrangement affects the load distribution in the spherical roller thrust bearing (e.g. the run-out of another bearing that induces radial forces)  
→  $P = F_a + X F_r$

For additional information (→ **page 85**)

$F_r > 0,55 F_a \rightarrow$  Contact the SKF application engineering service.

### Equivalent static bearing load

$F_r \leq 0,55 F_a \rightarrow P_0 = F_a + X_0 F_r$

$F_r > 0,55 F_a \rightarrow$  Contact the SKF application engineering service.

For additional information (→ **page 88**)

## 13 Spherical roller thrust bearings

Diagram 1

Minimum load requirements for spherical roller thrust bearings

### Temperature limits

The permissible operating temperature for spherical roller thrust bearings can be limited by:

- the dimensional stability of the bearing washers
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

#### Bearing washers

SKF spherical roller thrust bearings undergo a special heat treatment. The bearing washers are heat stabilized up to at least 200 °C (390 °F) for 2 500 h, or for brief periods at even higher temperatures.

#### Lubricants

Temperature limits for SKF greases are provided under *Lubrication* (→ [page 239](#)). When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ [page 244](#)).

### Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ [page 117](#)).

## Design of bearing arrangements

### Abutment dimensions

The abutment dimensions  $d_{a \min}$  and  $D_{a \max}$  listed in the product tables apply for axial bearing loads  $F_a \leq 0,1 C_0$ . If the bearings are subjected to heavier loads, it may be necessary to support the shaft and housing washers over their entire side faces ( $d_a = d_1$  and  $D_a = D_1$ ). For heavy loads, where  $P > 0,1 C_0$ , the shaft washer bore must be fully supported by the shaft, preferably by an interference fit. Even the housing washer should be radially supported ( $\rightarrow$  fig. 4).

For additional information about dimensioning washer supports, contact the SKF application engineering service.

### Recessed housing bore for bearings with a stamped cage

For bearings fitted with a stamped window-type steel cage, the housing bore must be recessed ( $\rightarrow$  fig. 5) to prevent the cage from contacting the housing during possible misalignment. SKF recommends the following guideline values for the diameter of that recess:

- $D + 15$  mm for bearings with an outside diameter  $D \leq 380$  mm
- $D + 20$  mm for bearings with an outside diameter  $D > 380$  mm

## 13 Spherical roller thrust bearings

### Axial clearance

SKF spherical roller thrust bearings must be subjected to a minimum load (→ *Minimum load*, **page 1082**). However, at relatively slow speeds, in the zone below the blue line (→ **diagram 1**, **page 1084**) the application can be designed to operate with a small axial clearance. For these applications, bearings with a modified shaft washer (designation suffix VUQ29) should be used. Small axial clearance enables simple and cost-effective bearing arrangements e. g. for horizontal shaft applications at relatively slow speeds, as no external preload is necessary.

For additional information about bearing arrangements with axial clearance, contact the SKF application engineering service.

### Lubrication

Generally, SKF spherical roller thrust bearings can be lubricated with oil or grease containing EP additives.

When lubricating with grease the roller end / flange contacts must be supplied with an adequate amount of grease. Depending on the application, this can be solved by filling the bearing and housing with grease, or by regular relubrication. For additional information, contact the SKF application engineering service.

#### Pumping effect in oil lubricated applications

Spherical roller thrust bearings create a pumping effect because of their internal design. The pumping effect creates a flow from the small to the large roller end face that can be taken advantage of in oil lubricated applications. The pumping action occurs in applications where the shaft is vertical (→ **fig. 6**) or horizontal (→ **fig. 7**) and should be considered when selecting the type of lubricant and sealing arrangement.

For high-speed applications that use bearings with a machined cage, SKF recommends using the oil injection lubrication method (→ **fig. 8**).

For additional information about lubricating spherical roller thrust bearings, contact the SKF application engineering service.

Fig. 6

Fig. 7

Fig. 8

## 13 Spherical roller thrust bearings

### Mounting

SKF spherical roller thrust bearings are separable, making it possible to mount the housing washer separately from the shaft washer, cage and roller assembly.

When a spherical roller thrust bearing with a machined cage is to be replaced by an E design bearing with a stamped window-type steel cage, and axial forces are transmitted via the cage guiding sleeve, a spacer ring must be inserted between the shaft abutment and the shaft washer (→ **fig. 9**).

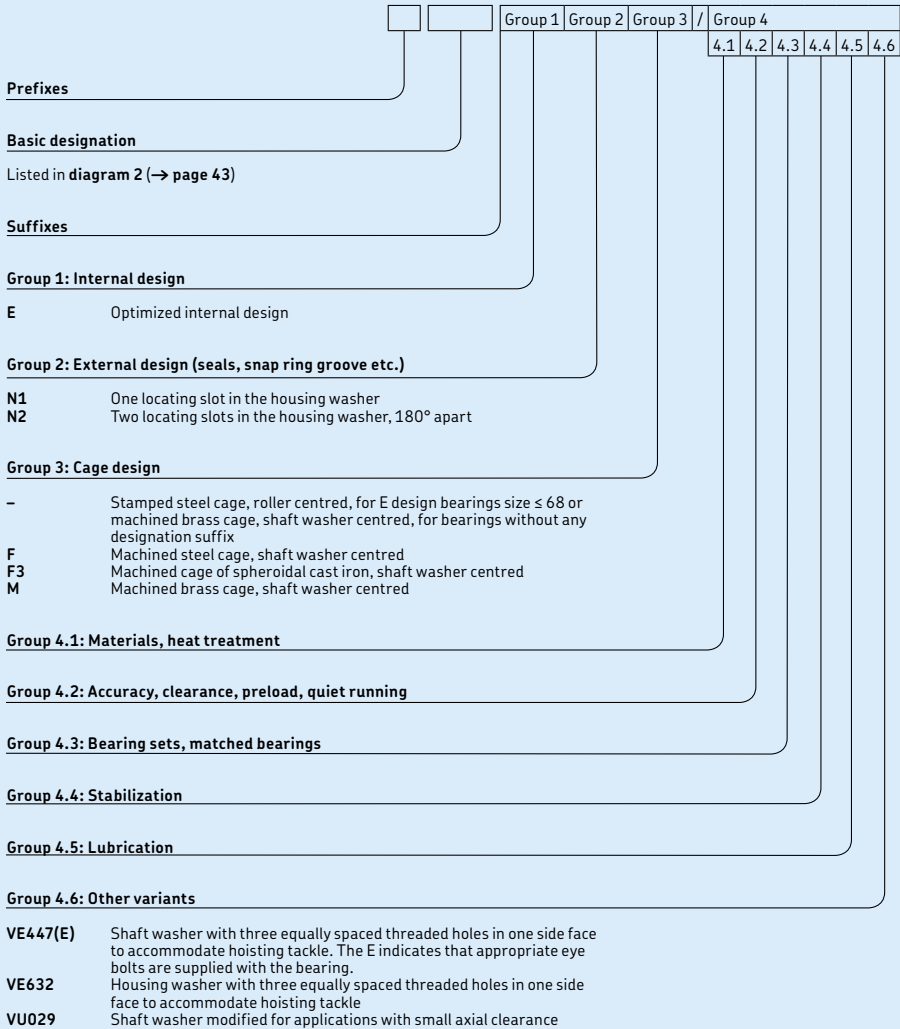

If an earlier B design SKF bearing, mounted with a spacer ring, is to be replaced, the spacer ring generally needs to be modified (→ **fig. 10**). The diameter  $d_{b2}$  (→ **product**

**tables**) of the spacer ring needs to be reduced for almost all bearing sizes.

The spacer ring must be hardened and its side faces should be ground. Appropriate spacer ring dimensions for SKF spherical roller thrust bearings are listed in the product tables.

## Designs and variants

Track runner bearings are designed to run on all types of tracks and to be used in cam drives, conveyor systems, etc. These bearings have a thick-walled outer ring, which enables them to accommodate high radial loads, while reducing distortion and bending stresses.

The outer ring running surface is crowned as standard. This is beneficial for applications where angular misalignment relative to the track may occur or where edge stresses need to be minimized. With the exception of single row cam rollers, track runner bearings are also available with a cylindrical (flat) outer ring running surface.

SKF supplies track runner bearings greased, sealed and ready to mount.

SKF supplies track runner bearings in many different types and designs, and for a wide variety of operating conditions and applications. The assortment comprises:

- cam rollers, internal design based on ball bearings
- support rollers, internal design based on needle or cylindrical roller bearings
- cam followers, internal design based on needle or cylindrical roller bearings

## Cam rollers

### Single row cam rollers

SKF single row cam rollers (→ fig. 1) are based on deep groove ball bearings in the 62 series. They are supplied greased and capped with a sheet steel reinforced NBR contact seal on both sides.

### Double row cam rollers

SKF double row cam rollers (→ fig. 2) are based on double row angular contact ball bearings in the 32 dimension series and have a 30° contact angle. They are supplied greased and capped with a sheet steel shield on both sides, which extends into a recess on the inner ring.

Fig. 1

Fig. 2

## Support rollers

### Support rollers without flange rings

SKF support rollers without flange rings (→ **fig. 3**) are designed for applications where associated components limit axial movement of the outer ring. Based on needle roller bearings, these support rollers are available with or without an inner ring. Support rollers with an inner ring have an inner ring that is slightly wider than the outer ring to avoid axial clamping of the outer ring. Support rollers without an inner ring are intended for arrangements where the pin or shaft is hardened and ground.

### STO and RSTO design support rollers

STO design support rollers have an inner ring, while RSTO design support rollers do not have an inner ring (→ **fig. 4**). Both designs are only available open (without seals). The components can be mounted separately, but the outer ring and the needle roller and cage assembly must always be kept together as supplied.

### NA 22...2RS and RNA 22...2RS design support rollers

NA 22...2RS design support rollers have an inner ring, while RNA 22...2RS design support rollers do not have an inner ring (→ **fig. 5**). The needle roller and cage assembly is guided axially between two integral flanges in the outer ring to form a non-separable unit. The inner ring of NA 22...2RS design support rollers can be mounted separately from the outer ring, roller and cage assembly. Both designs are supplied greased and capped with a sheet steel reinforced NBR contact seal on both sides.

Fig. 5

## 14 Track runner bearings

### Support rollers with flange rings

Support rollers with flange rings are non-separable units, designed for applications where there are axial loads, but no lateral (axial) support surfaces (→ **fig. 6**). These axial loads, which are induced when shafts are not horizontal or aligned properly, are accommodated by the flange rings. Depending on the design of the support rollers, the flange rings are pressed-on (NATR and NATV designs) or loose (NUTR, PWTR and NNTR designs).

### NATR and NATV design support rollers

NATR design support rollers are fitted with a needle roller and cage assembly, while NATV design support rollers have a full complement of needle rollers (→ **fig. 7**). The outer rings of both designs are guided axially by pressed-on flange rings. The narrow gap between the flange rings and the outer ring serves as a gap-type seal.

Both designs are also available with an axial sliding ring on both sides, identified by the designation suffix PPA (→ **fig. 8**). The axial sliding rings are made of PA66. In the radial direction, the sliding ring forms a narrow labyrinth seal with the outer ring, to protect against coarse contaminants. In the axial direction, the sliding ring serves as a contact seal to reliably retain grease in the bearing. This improves the lubrication conditions in the bearing, keeps friction and frictional heat low, and extends grease life.

Support rollers with axial sliding rings can accommodate somewhat heavier axial loads than those without axial sliding rings. Axial loads are induced when operating in an inclined or tilted position.

### NUTR .. A design support rollers

NUTR .. A design support rollers (→ **fig. 9**) are based on double row, full complement cylindrical roller bearings without an integral flange between the two roller sets. The outer ring has two integral flanges to guide the roller sets axially. A loose flange ring on both sides of the inner ring provides axial guidance for the outer ring via the roller sets. This enables NUTR .. A design support rollers to accommodate relatively heavy axial loads that are induced when operating in an inclined or tilted position.

A sheet metal angle ring is pressed into the outer ring shoulder on both sides and forms an effective labyrinth seal. The angle rings extend over the flange rings, making the bearing non-separable.

If heavy shock loads occur, support rollers with a reinforced outer ring should be used. These are identified by a bearing designation that has a four- or five-digit number instead of a two-digit number, e.g. NUTR 50110 A.

### PWTR ...2RS design support rollers

PWTR ...2RS design support rollers (→ **fig. 10**) are based on double row, full complement cylindrical roller bearings. Three integral flanges in the outer ring guide the two roller sets axially. A loose flange ring on both sides of the inner ring provides axial guidance for the outer ring via the roller sets. This, together with the relatively large grease quantity between the two roller sets, enable PWTR ...2RS design support rollers to accommodate relatively heavy constant axial loads that are induced when operating in an inclined or tilted position.

PWTR ...2RS design support rollers are supplied with an NBR contact seal on both sides. The seals are integral with the sheet metal angle rings and press against the flange rings. The angle rings are pressed into the outer ring shoulder. They extend over the flange rings, making the bearing non-separable.

If heavy shock loads occur, support rollers with a reinforced outer ring should be used. These are identified by a bearing designation that has a four- or five-digit number instead of a two-digit number, e.g. PWTR 50110.2RS.

### NNTR ...2ZL design support rollers

NNTR ...2ZL design support rollers (→ **fig. 11**) are based on double row, full complement cylindrical roller bearings. They are designed to accommodate very heavy radial loads. Three integral flanges in the outer ring axially guide the two roller sets. A loose flange ring on both sides of the inner ring provides axial guidance for the outer ring via the roller sets. This, together with the relatively large grease quantity between the two roller sets, enable NNTR ...2ZL design support rollers to accommodate relatively heavy constant axial loads that are induced when operating in an inclined or tilted position.

NNTR ...2ZL design support rollers are fitted with a lamellar seal on both sides. The seals are inserted into recesses in the shoulders of the flange rings and the outer ring, making the bearing non-separable.

### Cam followers

Instead of an inner ring, cam followers have a solid stud (pin) that is threaded so that the cam follower can be quickly and easily attached to appropriate machine components by means of a hexagonal nut.

SKF cam followers are available in three basic designs:

- KR design
- NUKR design
- PWKR design

All three cam follower designs have the same main dimensions. The differences are in their internal design, which make them suitable for various operating conditions. In contrast to ball and roller bearings, where the bearing size refers to the bore diameter  $d$ , for cam followers the size refers to their outside diameter  $D$ .

All designs are available with a concentric seat (→ **fig. 12**) or an eccentric collar (→ **fig. 13**) on the stud. An eccentric collar, which has a shrink-fit onto the stud, enables less stringent positioning tolerances to be specified for associated components. The values for the adjustable eccentricity are listed in the product tables. An eccentric collar is identified by the letter E at the end of the basic designation.

### KR design cam followers

KR design cam followers are fitted with a needle roller and cage assembly. They are also available with a full complement needle roller set (→ **fig. 14**), which is identified by the letter V at the end of the basic designation. The outer ring is axially guided by the pressed-on flange ring and the head of the stud, which also serves as an integral flange.

KR design cam followers without a designation suffix or with the designation suffix B (→ **fig. 15**) have a narrow gap between the outer ring and the two flanges that serves as a gap-type seal.

KR.. PPA, size  $\geq 30$

KR design cam followers are also available with an axial sliding ring made of PA66 on both sides, identified by the designation suffix PPA (→ **fig. 16**) or PPSKA (→ **fig. 17**). In the radial direction, the sliding ring forms a narrow labyrinth seal with the outer ring to protect against coarse contaminants. In the axial direction, the sliding ring serves as a contact seal to reliably retain grease in the bearing. This improves the lubrication conditions in the bearing, keeps friction and frictional heat low, and extends grease life.

Cam followers with axial sliding rings can accommodate somewhat heavier axial loads than those without axial sliding rings. Axial loads are induced when operating in an inclined or tilted position.

KR design cam followers, sizes 16 and 19, either without a designation suffix or with the designation suffix PPA have one slot in the head of the stud that enables the stud to be held in place by a screwdriver during mounting. In the centre of that slot is a relubrication hole for a press-in grease fitting or a plug if relubrication is not required (→ **Accessories, page 1109**). SKF also supplies these two sizes with a hexagonal recess in the head of the stud. They are fitted with an axial sliding ring on both sides and are identified by the designation suffix PPSKA (→ **fig. 17**).

KR design cam followers with the designation suffix B, sizes 22 and larger, have a hexagonal recess at each end of the stud (→ **fig. 15, page 1105**), enabling the cam follower to be held in place by a hexagonal key (Allen wrench)

during mounting. In the centre of each hexagon is a relubrication hole for a press-in grease fitting, if needed. Sizes 35 and larger can accommodate adapters from a central lubrication system (→ *Accessories*, **page 1109**).

#### NUKR .. A design cam followers

NUKR .. A design cam followers (→ **fig. 18**) are based on double row, full complement cylindrical roller bearings without an integral flange between the two roller sets. The stud head and pressed-on flange ring guide the outer ring axially via the roller sets. This enables NUKR .. A design cam followers to accommodate relatively heavy axial loads that are induced when operating in an inclined or tilted position.

A sheet metal angle ring is pressed into the outer ring shoulder on both sides to form an effective labyrinth seal.

NUKR .. A design cam followers have a hexagonal recess at each end of the stud, enabling the cam follower to be held in place by a hexagonal key (Allen wrench) during mounting. In the centre of each hexagon is a relubrication hole for a press-in grease fitting or an adapter from a central lubrication system (→ *Accessories*, **page 1109**).

#### PWKR ...2RS design cam followers

PWKR ...2RS design cam followers (→ **fig. 19**) are based on double row, full complement cylindrical roller bearings. The stud head and a pressed-on flange ring guide the outer ring axially via the roller sets. This enables PWKR ...2RS design cam followers to accommodate relatively heavy constant axial loads that are induced when operating in an inclined or tilted position.

PWKR ...2RS design cam followers are supplied with an NBR contact seal on both sides. The seals are integral with the sheet metal angle rings and press against the flange ring and the stud head. The angle rings are pressed into the outer ring shoulder.

PWKR ...2RS design cam followers have a hexagonal recess at both ends of the stud, enabling the cam follower to be held in place by a hexagonal key (Allen wrench) during mounting. In the centre of each hexagon is a relubrication hole for a press-in grease fitting or an adapter from a central lubrication system (→ *Accessories*, **page 1109**).

Accessories

Accessories provide SKF cam followers with reliable lubrication and location (→ table 1). Accessories, other than grease fittings and hexagonal nuts must be ordered separately.

Grease fittings

SKF supplies the appropriate grease fittings, that can be pressed into position, with each cam follower as standard (→ table 1). These are the only grease fittings that should be used. Dimensions are listed in table 2.

For KR design cam followers, sizes 16 and 19, the head of the grease fitting protrudes from the head end of the stud by 1,5 mm.

Hexagonal nuts

SKF supplies the appropriate hexagonal nuts with each cam follower as standard (→ table 1). They are in accordance with ISO 4032 or ISO 8673. These 8.8 strength class nuts are zinc galvanized to ISO 4042. Dimensions and recommended tightening torques are listed in table 3.

Plugs

The end of the relubrication hole in the stud of KR design cam followers, sizes 16 and 19, except those with the designation suffix PPSKA, can be plugged if relubrication is not required or if there is no space for the head of the grease fitting. Appropriate plugs (→ table 1) with a VD1 designation must be ordered separately.

### Adapters for connecting to a centralized lubrication system

AP design adapters enable cam followers to be relubricated via a centralized lubrication system. These adapters have a connection that accommodates, for example, 4 × 0,75 polyamide tubing in accordance with DIN 73378 (→ fig. 20). Appropriate adapters are listed in table 1 (→ page 1108), the dimensions are listed in table 4.

## Cages

Depending on their design and series, SKF track runner bearings are fitted with one of the cages shown in **table 5**. Double row cam rollers are equipped with two cages. The standard cage is not identified in the bearing designation.

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

## 14 Track runner bearings

### Lubrication

SKF track runner bearings are supplied greased. They are filled with the appropriate amount of a high-quality grease under clean conditions. The technical specifications of the greases are listed in **table 6**.

(R)STO design support rollers can be oil or grease lubricated. In applications where oil is used, SKF recommends thoroughly washing the initial grease fill from the bearing prior to operation.

### Relubrication requirements

Single row cam rollers are greased for the life of the bearing and cannot be relubricated.

Double row cam rollers are also greased for the life of the bearing under normal operating conditions. If subjected to moisture or solid contaminants, or if they run for long periods at temperatures above 70 °C (160 °F), they should be relubricated. When relubricating double row cam rollers, the grease should be applied slowly to avoid damaging the shields.

Support rollers and cam followers require little maintenance, but they should be relubricated regularly to achieve their full service life. SKF recommends relubrication while the initial grease fill still has its full lubricating properties. Support rollers and cam followers used in

applications where there are light loads, relatively slow speeds and clean surroundings, can operate for long periods before relubrication is required. Support rollers and cam followers that operate under contaminated and damp conditions at high speeds or at temperatures above 70 °C (160 °F) require more frequent relubrication. Full complement support rollers or cam followers require more frequent relubrication.

KR design cam followers, sizes 16 and 19, designation suffix PPSKA, cannot be relubricated.

### Relubrication facilities

SKF supplies all inner rings for support rollers and double row cam rollers with one lubrication hole, except for inner rings of the NNTR design support rollers, which have three lubrication holes when  $d \leq 90$  mm or six lubrication holes when  $d \geq 100$  mm. If suitable ducts are provided in the pin, the bearings are easy to relubricate.

Cam followers can be relubricated via ducts in the stud. Depending on series and size, there are up to three positions for relubrication (→ **fig. 21**). Detailed information about the positions can be obtained from the product tables (→ **page 1140**). Positions 1 and 2 can take the grease fitting supplied with the cam follower. Position 3 should be used when relubricating via ducts in the adjacent components. Positions not used for relubrication should be closed with a grease fitting or a plug.

For cam followers, size  $\geq 35$ , positions 1 and 2 can be connected to a central lubrication system (→ *Accessories*, **page 1109**).

## Loads

	Single row cam rollers	Double row cam rollers	Support rollers
<b>Dynamic loads</b>	Compared to a typical rolling bearing, where the outer ring is fully supported in a housing, a track runner bearing has only a small contact area between its outside surface and the track. The actual contact area depends on the applied radial load and the profile of the runner surface. Deformation of the outer ring, caused by this limited contact, alters the load distribution in the bearing, which affects load carrying ability. The basic load ratings listed in the product tables take this into account. ...		
<b>Static loads</b>	The permissible static load for a track runner bearing is determined by the smaller of the values $F_{Or\ max}$ and $C_0$ (→ <b>product tables</b> ). If requirements for smooth running are below normal, the static load may exceed $C_0$ , ...		
<b>Axial loads</b>	Cam rollers are intended for predominantly radial loads. If an axial load acts on the outer ring, as when the cam roller runs against a guide flange, it produces a tilting moment and the service life of the cam roller may be reduced as a consequence.	Support rollers with flange rings can generally accommodate axial loads that are induced when operating in an inclined or tilted position. The magnitude of permissible load depends on the internal design.	
<b>Minimum load</b>	$F_{rm} = 0,0167 C_0$		
For additional information (→ page 86)	The weight of the components supported by the bearing, together with external forces, generally exceed the requisite minimum load. If this ...		
<b>Equivalent dynamic bearing load</b>	$F_a/F_r \leq e$ → $P = F_r$	$F_a/F_r \leq 0,8$ → $P = F_r + 0,78 F_a$	$P = F_r$
For additional information (→ page 85)	$F_a/F_r > e$ → $P = 0,46 F_r + Y F_a$	$F_a/F_r > 0,8$ → $P = 0,63 F_r + 1,24 F_a$	
<b>Equivalent static bearing load</b>	$P_0 = 0,6 F_r + 0,5 F_a$ $P_0 < F_r \rightarrow P_0 = F_r$	$P_0 = F_r + 0,66 F_a$	$P_0 = F_r$
For additional information (→ page 88)

## Temperature limits

The permissible operating temperature for track runner bearings can be limited by:

- the dimensional stability of the bearing rings and rolling elements
- the cage
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing rings and rolling elements

SKF track runner bearings undergo a special heat treatment. The bearings are heat stabilized up to at least:

- 120 °C (250 °F) for single row cam rollers
- 150 °C (300 °F) for double row cam rollers
- 140 °C (280 °F) for support rollers and cam followers

### Cages

Steel cages can be used at the same operating temperatures as the bearing rings and rolling elements. For temperature limits of PA66 cages, refer to *Cage materials* (→ **page 152**).

### Seals

The permissible operating temperature for seals depends on the material:

- NBR seals:  
–40 to +100 °C (–40 to +210 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- PA66 sliding rings:  
–30 to +100 °C (–20 to +210 °F)

### Lubricants

Temperature limits for greases used in SKF track runner bearings are provided in **table 6** (→ **page 1112**). Temperature limits for other SKF greases are provided under *Lubrication* (→ **page 239**)

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ **page 244**).

## Speed limits

Values for the limiting speeds are listed in the product tables. For additional information about the limiting speed, refer to *Speeds* (→ **page 117**).

## Design of associated components

### Pins

Cam rollers and support rollers generally operate under conditions of stationary inner ring load. For this type of load, and if easy displacement of the inner ring is required, the pin or shaft should be machined to tolerance class g6 (E).

The recommended pin tolerance class for support rollers without an inner ring is k5 (E). To exploit the full load carrying capacity of support rollers, the raceways on the pins should have the same hardness and surface finish normally found on bearing raceways. For additional information, refer to *Raceways on shafts and in housings* (→ page 210).

### Attachment holes for studs

The holes in the adjacent part of machinery to accommodate the stud or eccentric collar of a cam follower should be machined to tolerance class H7 (E). If the requisite tightening torque for the hexagonal nut (→ table 3, page 1109) cannot be achieved or the cam followers are subjected to shock loads, the stud or eccentric collar should be mounted with an interference fit. The lead-in chamfer of the holes should be  $\leq 0,5 \times 45^\circ$ .

## Support surfaces

### Cam rollers

Cam rollers that must accommodate heavy axial loads should be supported over the entire inner ring side face (→ fig. 22). The support surface should be dimensioned according to diameter  $d_1$  (→ product tables).

### Support rollers

The outer ring support surfaces of support rollers without flange rings must be fine turned, free of burrs and clean. Unhardened surfaces should extend to at least half the outer ring side face (→ fig. 23) while hardened surfaces may be smaller.

Heavily loaded support rollers with flange rings should be axially supported over the entire flange ring side faces (→ fig. 24). The support surface should be dimensioned according to diameter  $d_1$  (→ product tables).

### Cam followers

The flange ring that is pressed onto the stud shank should be supported axially over its entire side face (→ fig. 25). The support surface should be dimensioned according to diameter  $d_1$  (→ product tables). The strength of the material should be sufficiently high to accommodate the tightening torque.

Fig. 22

Fig. 23

### Guide flanges for cam rollers

For rails or cams with guide flanges, the recommended flange height  $h_a$  (→ **fig. 22**) should be:

$$h_a \leq 0,5 (D - D_1)$$

This helps to avoid damage to the seals or shields fitted in the outer ring. The values for the outer ring diameters  $D$  and  $D_1$  are listed in the product tables.

### Axial gap

Support rollers without flange rings, but with an inner ring, and support rollers with flange rings must be located without any axial gap (→ **fig. 24**).

Support rollers without an inner ring must have an axial gap  $\geq 0,2$  mm between the outer ring and support surface (→ **fig. 23**).

Fig. 24

Fig. 25

## Mounting

### Support rollers

SKF recommends positioning the lubrication hole in the unloaded zone of the support roller inner ring, except for PWTR and NNTR design support rollers, which have the lubrication holes in the empty space between the two roller sets.

When mounting the outer ring assembly and inner ring separately, care must be taken not to damage the seal lips.

### Cam followers

Cam followers can be attached to associated components (→ **fig. 25, page 1121**) using the hexagonal nut (→ **table 3, page 1109**) supplied together with the cam follower. Spring washers, which are not supplied by SKF, can be used to secure the nuts.

The nuts should be tightened to the recommended torque values listed in **table 3** (→ **page 1109**). The recommended tightening torques enable the full load carrying capacity of the cam follower to be exploited. If heavy vibrations occur, the cam followers can be located using self-locking nuts in accordance with ISO 10511 or special lock washers.

For self-locking nuts, a higher tightening torque must be applied. Follow the recommendations of the nut manufacturer.

Most cam followers (all for sizes  $\geq 22$ ) have a hexagonal recess in the stud head and can be held in place by a hexagonal key (Allen wrench) while the nut is being tightened. Some cam follower designs of the small sizes 16 and 19 have a slot in the stud head instead, and can be held in place by a screwdriver. For additional information, refer to the illustrations in the product tables (→ **page 1140**).

Depending on the mounting conditions, cam followers with an eccentric collar can be adjusted to the required eccentricity via the slot or the hexagonal recess.

Do not hit the head of the stud as damage to the cam follower may result.

SKF recommends positioning the lubrication hole in the stud head in the unloaded zone of the cam follower. The position of this hole corresponds to the marking on the head end of the stud.

The lubrication hole in position 3 (→ **fig. 21, page 1113**) may be used to incorporate a locking device to prevent the stud from turning.

When inserting a plug, it should be pressed into place using a mandrel (→ **fig. 26**).

## 15A Sensor bearing units

### Motor encoder units

Monitoring the status of rotating components accurately is essential for many applications. This is particularly true for AC motors that require encoders to continuously measure speed and the direction of rotation.

SKF motor encoder units (→ **fig. 1**) are compact and ready-to-mount units that combine active sensor technology with an SKF Explorer deep groove ball bearing. These units, which can be installed at either bearing position in an AC motor, are only 6,2 mm wider than the corresponding standard deep groove ball bearing (→ **fig. 2**). SKF motor encoder units can provide a signal resolution ranging from 32 to 80 digital pulses per revolution. They are available for shaft diameters ranging from 15 to 45 mm.

#### Designs and variants

SKF motor encoder units (→ **fig. 3**) are compact, integrated units consisting of:

- an SKF Explorer deep groove ball bearing in the 62 series with a snap ring groove in the outer ring (→ *Deep groove ball bearings*, **page 295**) and an RS1 contact seal
- an impulse ring
- a sensor body
- a cable outlet and connecting cable

The impulse ring, which attaches to the inner ring of the bearing, is a composite magnetized

ring that contains between 32 and 80 north and south poles. The number of poles depends on the size of the bearing. The sensor body, which is attached to the outer ring, protects the patented SKF Hall effect cell. The multi-wire connecting cable extends in the radial direction.

The bearing is protected by a contact seal on one side. On the opposite side of the bearing, the impulse ring and sensor body create an effective labyrinth seal to keep lubricant in and solid contaminants out of the bearing.

**Sensor technology**

SKF motor encoder units use a compact and robust sensor that produces an incremental encoder signal. The sensor is accurate down to zero r/min. An integrated active circuit (requiring an external voltage supply) in the sensor body contains two Hall effect cells that produce an output signal consisting of two square waves (→ fig. 4).

The signals can be interpreted by motor controllers in different ways:

- The direction of rotation can be determined from the phase shift, when the rising edge of a signal first appears.

- Slow speeds can be determined by measuring the time between two electrical events, events being the rising and falling edge on either square wave.
- High speeds can be measured by counting the number of electrical events within a given time period.

The two square waves are 90° out of phase with each other. This phase shift changes sign with the direction of rotation. Fig. 4 shows the general specifications of the signal. The presence of two signals in quadrature enables a processing unit to multiply the number of angular position increments per revolution. For example, using a standard SKF sensor bearing with 64 pulses per revolution and a standard electronic interface that can detect the rising (Low/High) and falling (High/Low) times of each of the two signals, it is possible to obtain 256 electrical events per revolution, which translates to an angular resolution of 1,4° (→ fig. 4).

SKF motor encoder units provide accurate and reliable signals for effective motor control and are 100% tested for period accuracy, duty cycle and phase shift during manufacture.

## 15A Sensor bearing units

### Cable connection

SKF motor encoder units are available as standard with either a free cable end (designation suffix 008A, → **fig. 5**) or an AMP Superseal™ connector (AMP Nos. 282106-1 and 282404-1, designation suffix 108A, → **fig. 6**). The standard cable lengths are listed in the product table.

For alternative connectors or cable lengths, contact the SKF application engineering service.

### Grease fill

SKF motor encoder units are filled with a high-quality grease under clean conditions, suitable for the most common operating conditions of electric motors. Grease specifications are listed in **table 4** (→ **page 305**), under WT grease.

Motor encoder units are considered relubrication-free. The grease life in the bearing can be calculated according to the method described under *Grease life for capped bearings* (→ **page 306**).

### Motor encoder units for extreme operating conditions

Magnetic sensors have temperature and motor power limits. For applications where magnetic sensors are not practical, high-performance inductive technology can be used instead. Inductive sensors use coils to sense the rotation of a specially designed induction tooth ring.

For additional information about motor encoder units for extreme operating conditions, contact the SKF application engineering service.

### Product data

#### Requirements for the receiving interface

The receiving interface must be able to process the signals, which are provided via open collector circuits. A typical schematic drawing is shown in **fig. 7**. Output signal features are listed in **table 1**. The phase shift is the delay between the two signals' rise events (→ **fig. 4**, **page 1153**). It is  $1/4$  of the period, or 90 electric degrees. The duty cycle value is the high state of the signal compared to the full period (→ **fig. 4**, **page 1153**). It is 50% nominal.

**Power supply**

SKF motor encoder units require a regulated voltage supply, which can range from 5 to 16 V DC. For applications above 16 volts, contact the SKF application engineering service.

**Resistors**

Pull-up resistors should be placed between the voltage supply and the conductors for the output signals to limit the output current to 20 mA. Recommended pull-up resistors are listed in **table 2**.

The application load resistance between the ground line and the conductors for the output signals should be at least 10 times higher than the resistance of the pull-up resistor. This helps to keep the output signals readable.

**Detecting direction of rotation**

A positive phase shift corresponds to signal B rising before signal A and indicates the inner ring rotating clockwise when viewed from the sensor side.

**Electromagnetic compatibility**

SKF motor encoder units can be used in systems operating in very arduous electromagnetic environments as described in the international standard IEC 61000-6-2.

**High-performance filtering**

All standard SKF motor encoder units are protected with high-performance filtering, so they can adapt to the electric environment typically found in industrial and automotive applications. Motor encoder units with a free cable end have the filter included in the overmoulding on the cable. Units with an AMP Superseal™ connector have the filter integrated in the connector.

For additional information (→ page 149)	

### Loads

For information about minimum load and equivalent bearing loads, refer to *Deep groove ball bearings* (→ *Loads*, page 316).

### Temperature limits

SKF motor encoder units have been tested successfully under various speeds and loads:

- 500 hours at 120 °C (250 °F) with intermittent peaks of up to 10 minutes at 150 °C (300 °F)
- 100 hours at –40 °C (–40 °F)

The permissible operating temperature for SKF motor encoder units can be limited by:

- the dimensional stability of the bearing rings and balls
- the cage
- the seal
- the lubricant
- the sensor

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

### Bearing rings and balls

The bearing rings and balls undergo a special heat treatment. The bearings are heat stabilized up to at least 120 °C (250 °F).

### Cages

Steel cages can be used at the same operating temperatures as the bearing rings and balls. For temperature limits of polymer cages, refer to *Cage materials* (→ page 152).

### Seal

The permissible operating temperature for NBR seals is –40 to +100 °C (–40 to +210 °F).

### Lubricant

Temperature limits for the WT grease used in SKF motor encoder units are provided under *Deep groove ball bearings* (→ table 4, page 305).

### Sensor

The permissible operating temperature for the sensor is  $-40$  to  $+150$  °C ( $-40$  to  $+300$  °F).

For applications where the voltage supply is above 18 V and temperature exceeds 85 °C (185 °F), SKF recommends placing a 1 kΩ resistor in series with the supply line to limit heat generated by the electronic components.

### Permissible speed

The permissible operating speed is limited by the contact seal in the bearing. The sensor can accurately detect speeds from zero r/min up to the limiting speed listed in the product table for the individual sensor unit.

### System design

In principle, SKF motor encoder units can be incorporated in designs in the same way as SKF deep groove ball bearings. Some specific recommendations are described below. For additional information about electric motor applications, refer to the SKF handbook *Rolling bearings in electric motors and generators*.

### Cable outlet

The cable emerges radially from the motor encoder unit. A sufficiently dimensioned cable duct must be provided in the bearing housing or housing cover. The radial notch in the housing should have a width in the circumferential direction of 15 to 20 mm (→ fig. 8).

### Motor encoder units in the non-locating bearing position

SKF recommends using motor encoder units in the non-locating bearing position (→ fig. 9). However, there is a risk that the outer ring can spin in the housing bore, especially if vibration is a factor. Therefore, SKF recommends placing an O-ring in the snap ring groove to help prevent the outer ring from spinning, which could otherwise damage the cable.

Fig. 8

Fig. 9

## 15A Sensor bearing units

### Motor encoder units in the locating bearing position

When using motor encoder units in the locating bearing position, the impulse ring, sensor body and connecting cable should not be subjected to any axial load, whenever possible. When the bearing is subjected to axial loads that act in both directions, the motor encoder unit should be mounted in such a way that the heavier axial load is transmitted to the bearing outer ring side face opposite the sensor (→ **fig. 10**).

Motor encoder units can be located axially in the housing in different ways:

- with a snap ring in the outer ring and a cover bolted to the housing (→ **fig. 11a**)
- with a spacer sleeve and a snap ring in the housing (→ **fig. 11b**)
- with a cover engaging the outer ring (→ **fig. 11c**)

Motor encoder units with  $d \leq 25$  mm can only be located axially via a snap ring in the outer ring.

### Motor encoder units in “floating” bearing systems

When using motor encoder units in “floating” bearing systems (→ **page 164**), the outer ring should be prevented from spinning by placing an O-ring in the snap ring groove. The motor encoder unit should be mounted in such a way that the axial load acts on the bearing outer ring side face opposite the sensor.

Fig. 10

Fig. 11

Fig. 12

## Mounting

SKF motor encoder units must be handled with care to avoid damaging the bearing, sensor and connecting cable. Never apply any force on the cable, cable outlet, sensor body or impulse ring.

On request, SKF can provide assistance in optimizing the mounting and connecting processes. For additional information, contact the SKF application engineering service.

General mounting advice for SKF deep groove ball bearings is available online at [skf.com/mount](http://skf.com/mount).

### Mounting a unit on a shaft

Motor encoder units are typically mounted with an interference fit on the shaft. They can be pressed onto the shaft. The mounting force should be applied via a mounting sleeve or dolly abutting the inner ring side face (→ fig. 12).

To facilitate mounting, the bearing inner ring can be heated. Heating should only be done with a temperature-controlled electric hotplate. The bearing should be placed on a mandrel to effectively heat the inner ring (→ fig. 13). The seal should be placed in the lower position to avoid grease leaking out of the bearing. Induction heaters should not be used to heat motor encoder units as damage to the electronic components may result.

SKF does not recommend heating a motor encoder unit above 80 °C (175 °F).

Fig. 13

## 15A Sensor bearing units

### Mounting a unit into a housing

When motor encoder units have to be mounted into a housing with an interference fit, they can be pressed into the housing or the housing should be heated. The mounting force should be applied via a mounting sleeve or dolly abutting the outer ring side face or a snap ring fitted on the outer ring (→ **fig. 14**).

In typical electric motor applications, the bearing can be moved into position by using bolts to pull the motor shield and cover together (→ **fig. 15**).

### Cable connection

The cable should be protected by a duct to prevent it from making sharp turns, being pinched or making contact with any moving parts. To avoid any interference with the sensor signal, do not place the connector near other power cables or wires.

## 15A Sensor bearing units

### Roller encoder units

SKF roller encoder units are plug-and-play sensor bearing units designed for applications with outer ring rotation. The encoder units incorporate a sealed 6201 SKF Explorer deep groove ball bearing. They can be easily integrated into pulleys, cams, rollers or wheels to provide a compact outer ring rotation encoder assembly (→ **fig. 16**). The sealed bearing is lubricated for the life of the bearing. On request, SKF can supply roller encoder units complete with customized gears, wheels or pulleys. Basic data for the SKF roller encoder unit are listed in **table 3**. For detailed specifications, contact the SKF application engineering service.

#### Sensor technology

SKF roller encoder units use similar sensors as SKF motor encoder units (→ **page 1152**). They provide two signals, which can be used to determine relative position, speed, acceleration and direction of movement. The requirements for the receiving interface are the same as for SKF motor encoder units (→ **page 1152**).

## Other sensor bearing units

The SKF assortment of sensor bearing units is not limited to motor and roller encoder units. SKF has developed several solutions addressing specific applications, where sensor integration is a major added value. For additional information about these application specific sensor bearing units, contact the SKF application engineering service.

### Steering encoder units

SKF steering encoder units (→ **fig. 17**) are plug-and-play steering input devices for steer-by-wire systems. They combine reliable encoder technology with the simplicity of plug-and-play component packaging.

#### Designs and variants

SKF steering encoder units are based on well-proven SKF technologies. They have been designed from the inside out, starting with bearing encoder technology, to precisely monitor steering. From there, a friction torque device, mechanical interface for mounting and a shaft to connect the steering wheel are added to create a complete unit. The friction torque device provides feedback to the operator by providing adequate resistance in the steering wheel.

The units contain a sealed SKF Explorer deep groove ball bearing to provide long service life and reliable performance. They do not require any adjustment or relubrication during their expected service life and are considered

maintenance-free. They reliably fulfil the demands of industrial and off-highway vehicle steer-by-wire systems.

SKF steering encoder units are supplied ready to mount. Connection to a steer-by-wire system is achieved by plugs. Available steering encoder units are listed in **table 4**. For additional information about SKF steering encoder units, contact the SKF application engineering service.

## 15A Sensor bearing units

### Sensor technology and electrical data

SKF steering encoder units use non-contact incremental sensors to track the movement of the steering wheel. These magnetic sensors do not wear, are protected from external influences, and are designed to provide maximum service life. SKF steering encoder units are designed to support the safety requirements of safety related control systems in accordance with ISO 13849. They contain two sets of sensors to provide redundancy.

SKF steering encoder units provide two independent sets of square wave signals (→ **fig. 18**) via open collector circuits. They require a regulated voltage supply, which can range from 5 to 12 V DC. Pull-up resistors should be placed between the voltage supply and the conductors for the output signals to limit the output current to 20 mA. Recommended pull-up resistors are listed in **table 2** (→ **page 1155**). The application load resistance between the ground line and the conductors for the output signals should be at

least 10 times higher than the resistance of the pull-up resistor. This keeps the output signals readable.

### Units providing absolute position information

For applications where a combination of absolute position information, variable steering feel and active end stops are required, SKF can provide customized steering units. For additional information about available designs, contact the SKF application engineering service.

### Sensor units for motor control of hybrid and electric vehicles

Brushless permanent magnet synchronous motors require a sensor that provides the position of the rotor with a high degree of accuracy to enable accurate motor torque control and to achieve maximum efficiency and dynamics. These permanent magnet motors use either direct drive control or sine wave control. SKF sensor units can contribute to optimized motor efficiency for both systems.

#### Units for direct drive control

For direct drive control, SKF supplies commutation units delivering three signals, each with a 120° phase shift. The number of pulses per revolution matches the number of rotor pole pairs. These units comply with the speed and temperature requirements typical for power steering applications, high-speed spindles and small brushless electric drives.

#### Units for sine wave control

For sine wave control, SKF supplies sensor bearing units providing the shaft angle position in real time within the entire motor speed range. These integrated units provide a signal comparable to the one provided by a resolver and can therefore be used by the motor controller's software. The shaft angle position is communicated via a sinus/cosinus signal.

SKF can adapt the electronics to comply with the interface of the application. The units can provide either an analogue or a digital encoder-like output signal. The units are more compact and cost-effective than inductive resolvers. They are easy to mount and do not require special shaft or housing accuracy.

### Sensor units for angular position sensing in off-highway vehicles

Articulated joints, steer-by-wire systems or GPS tracking systems in off-highway vehicles require absolute position sensors to measure the angle between two elements. SKF can supply units providing a high-resolution absolute position signal, even under arduous environmental conditions.

Absolute position sensor solutions are tailored to customer requirements. SKF can propose a modular mechanical and electronic interface to the application to deliver a compact plug-and-play unit, not requiring intrusive modifications to the existing mechanical, electric or electronic architecture.

## 15B Bearings for extreme temperatures

Extreme temperature rolling bearings are designed to reduce machine operating costs, extend maintenance intervals and provide a high degree of operational reliability within a wide range of temperatures. The SKF assortment of extreme temperature bearings and bearing units includes:

- deep groove ball bearings (→ **fig. 1**)
- Y-bearings (insert bearings, → **fig. 2**)
- Y-bearing units (→ SKF catalogue *Y-bearings and Y bearing units*)
- SKF DryLube bearings (→ **page 1191**)

Bearings for extreme temperatures listed in this catalogue constitute the basic SKF assortment. On request, SKF can supply other extreme temperature bearings to meet the needs of a particular application. For information about these engineered products, contact the SKF application engineering service.

## Extreme temperature variants

Every extreme temperature application has its own unique challenges. As a fact, SKF has developed a number of variants that help to provide excellent performance based on the operating conditions of the application. The typical variants are listed in **table 1**. For additional information, contact the SKF application engineering service.

## Deep groove ball bearings for extreme temperatures

SKF deep groove ball bearings for extreme temperatures correspond in design to standard single row deep groove ball bearings of the same size. They have no filling slots and can accommodate normal axial loads in addition to radial loads. The radial internal clearance is a multiple of C5 to prevent the bearings from seizing, even when they cool rapidly. All surfaces of the bearing and shields are manganese phosphated to enhance adhesion of the lubricant to the metal and provide additional protection against corrosion.

SKF deep groove ball bearings for extreme temperatures are available in the variants listed in **table 1**. Typically, the bearings have a shield on both sides (designation suffix 2Z). The VA201 variant is also available as an open bearing (→ **fig. 3, page 1172**).

Shields prevent the ingress of solid contaminants into the bearing. The shields on a 2Z/VA201 bearing enable the bearing to be filled with twice the amount of polyalkylene glycol/graphite lubricant found in an open VA201 bearing.

## Y-bearings for extreme temperatures

Except for the cage and seals, SKF Y-bearings (insert bearings) for extreme temperatures correspond in design to standard Y-bearings with grub screws in the YAR 2-2F series. The bearings have a shield and a flinger on both sides to prevent the ingress of solid contaminants into the bearing. The radial internal clearance is twice the C5 clearance of same-sized deep groove ball bearings. All surfaces of the bearing and the shields and flingers are manganese phosphated to enhance adhesion of the lubricant to the metal and provide additional protection against corrosion.

SKF Y-bearings for extreme temperatures are available in the VA201 and VA228 variants (→ fig. 4).

## Bearing data

	Deep groove ball bearings for extreme temperatures	Y-bearings for extreme temperatures
<b>Dimension standards</b>	Boundary dimensions: ISO 15	Boundary dimensions: ISO 9628
<b>Tolerances</b>	Normal Values: ISO 492 (→ <b>table 3, page 137</b> )	Normal, except the bore and outside diameter Values: ISO 492 (→ <b>table 3, page 137</b> ) Values for the bore and outside diameter (→ <b>table 2, page 1174</b> )
For additional information (→ <b>page 132</b> )	Due to the special surface treatment of the bearings, there may be slight deviations from the standard tolerances. These deviations do not effect mounting or bearing operation.	
<b>Internal clearance</b>	Multiples of C5	Twice C5 of deep groove ball bearings in accordance with ISO 5753-1
For additional information (→ <b>page 149</b> )	Values (→ <b>table 3, page 1174</b> ) are valid for unmounted bearings under zero measuring load.	
<b>Misalignment</b>	≈ 20 to 30 minutes of arc	
	The above values apply only when the bearings rotate slowly. The permissible angular misalignment between the inner and outer ring depends on the size and internal design of the bearing, radial internal clearance in operation and the forces and moments acting on the bearing. As a result, only approximate values are listed here. Any misalignment increases bearing noise and reduces bearing service life.

### Selecting bearing size

As bearings for extreme temperatures typically rotate at slow speeds, the requisite bearing size can be determined based on the basic static load rating  $C_0$  (→ **product tables**). The bearing selected should have a  $C_0$  value  $\geq$  the requisite value.

#### Calculating the requisite basic static load rating

$$C_{0\text{req}} = 2 \frac{P_0}{f_T}$$

$$P_0 = 0,6 F_r + 0,5 F_a$$

$$P_0 < F_r \rightarrow P_0 = F_r$$

#### Symbols

$C_{0\text{req}}$  = requisite basic static load rating [kN]  
 $F_a$  = axial load [kN]  
 $F_r$  = radial load [kN]  
 $f_T$  = temperature factor (→ **table 4**)  
 $P_0$  = equivalent static bearing load [kN]

## Design of associated components

The shields in 2Z/VA208 and 2Z/VA228 design deep groove ball bearings guide the graphite cage axially. Therefore, the shields should be supported by the housing shoulder or a spacer ring with a bore diameter smaller than the outer ring shoulder diameter  $D_2$  (→ **product tables**). If this is not possible, a support washer with the appropriate bore diameter should be installed between the bearing and housing shoulder or spacer ring (→ **fig. 5**).

Table 4

### Temperature factor $f_T$

Operating temperature		Factor $f_T$
$^{\circ}\text{C}$	$^{\circ}\text{F}$	
150	300	1
200	390	0,9
250	480	0,75
300	570	0,6
350	660	0,45

### Maintenance

Bearings for extreme temperatures with a shield on both sides do not have a relubrication facility as they are lubricated for the life of the bearing.

Open VA201 design deep groove ball bearings should be inspected after some six months of operation. It is sufficient to open the housing, or in the case of kiln trucks, to withdraw the wheel with the bearing from the journal and to remove contaminants. If there is no longer a lubricant film indicated by a shiny metallic track on the raceways, the bearing should be relubricated using the original high-temperature paste.

Prior to relubrication, the bearing should be cleaned carefully. Do not spin the bearings when drying them with compressed air.

### Designation system

Refer to *Designation system* in the relevant product chapter (→ **page 320** for deep groove ball bearings and **page 456** for Y-bearings).

Additional designation suffixes used with SKF bearings for extreme temperatures are explained in the following.

- VA201** Bearing for extreme temperatures with a stamped steel cage, lubricated with a polyalkylene glycol/graphite mixture
- VA208** Bearing for extreme temperatures with a segmented cage made of graphite
- VA228** Bearing for extreme temperatures with a coronet cage made of graphite
- 2F** Shield and flinger on both sides
- 2Z** Shield on both sides
- W** Bearing without lubrication hole(s)

## 15C Bearings with Solid Oil

In most applications, standard greases and oils provide an adequate amount of lubricant to a bearing. However, in cases where accessibility to the bearing for relubrication purposes is impractical or impossible, Solid Oil is an excellent solution. Solid Oil can also be used effectively in applications where premature bearing failure is the result of high levels of contamination.

Typical conditions where Solid Oil is used include:

- wet and dirty environments
- vertical shaft arrangements
- applications exposed to g-forces
- special hygienic requirements
- oscillating movements
- bearings that are difficult to access for relubrication

## Features of Solid Oil

Solid Oil is an oil-saturated, polymer matrix that fills the entire free space in the bearing, encapsulating both the rolling elements and cage(s). The polymer material has a porous structure, with millions of micro-pores, to hold the lubricating oil. The pores are so small that the oil is retained in the material by surface tension. As the oil-filled polymer material is injected into the bearing, a very narrow gap forms around the rolling elements and raceways enabling the bearing components to rotate freely.

When Solid Oil slides against the rolling elements or raceways of a bearing, the metal is coated with an even and consistent film of oil. Then, with only a moderate increase in operating temperature, oil is pushed toward the surface of the polymer matrix. This “flow” of oil within the polymer matrix occurs because the oil has a higher coefficient of thermal expansion than the polymer matrix and because the viscosity of the oil decreases with increasing temperature. When the bearing stops running, excess oil is reabsorbed into the polymer matrix.

A bearing with Solid Oil contains two to four times more oil than conventional grease lubricated bearings. This is because the bearing is entirely filled with Solid Oil, whereas a grease lubricated bearing normally operates with approximately one third of its free space filled with grease.

Because Solid Oil fills the bearing entirely, it is difficult for solid or liquid contaminants to reach the bearing contact surfaces, even without bearing seals. In highly contaminated environments, however, SKF recommends using bearings with Solid Oil and integral contact seals.

## Bearings and bearing units with Solid Oil

Most SKF ball and roller bearings as well as bearing units (→ **fig. 1**) can be supplied with Solid Oil.

Some needle roller bearings and bearings fitted with a large-volume cage are less suitable for Solid Oil because there is too little free space left for Solid Oil inside the bearing.

### Solid Oil variants

The standard oil used for Solid Oil is a high-quality synthetic oil (designation suffix W64, → **table 1**), which meets the needs of most applications.

Oils with other viscosities and characteristics are also available (→ **table 1**). These special oils or additives are typically used in the following applications:

- food and pharmaceutical manufacturing and packaging (designation suffix W64F)

- low temperature applications (designation suffix W64L)

For additional information about Solid Oil, contact the SKF application engineering service.

### Sealing solutions

Deep groove ball bearings with Solid Oil are available capped with one of the following sealing solutions:

- a shield on one side (designation suffix Z)
- a contact NBR seal on both sides (designation suffix 2RS1 or 2RSH)

For additional information, refer to *Sealing solutions* (→ page 300).

For other capped bearings and bearing units with Solid Oil, refer to the product chapter of the relevant standard bearing.

### Bearing data

#### Dimension standards, tolerances, internal clearance

Dimensions, tolerances and internal clearance of bearings or units with Solid Oil are the same as for the corresponding standard products.

### Loads

#### Minimum load

The weight of the components supported by the bearing, together with external forces, generally exceed the requisite minimum load. If this is not the case, the bearing must be subjected to an additional radial load.

The minimum load for bearings with Solid Oil should be slightly higher than the minimum load for standard bearings. Recommendations for calculating the requisite minimum loads for the different standard bearing types are provided in the relevant product chapter.

#### Load carrying capacity

The basic dynamic and static load ratings for bearings with Solid Oil are the same as for same-sized standard bearings.

### Temperature limits

The temperature limits for bearings with Solid Oil are valid for both open and capped bearings. The relevant limits are:

- minimum (→ **table 1, page 1187**)
- maximum 85 °C (185 °F) for continuous operating conditions
- maximum 95 °C (205 °F) for intermittent operating conditions

If bearings with Solid Oil are to be hot mounted, SKF does not recommend heating the bearing above 80 °C (175 °F). However, if higher temperatures are necessary, make sure that the temperature does not exceed the permissible temperature of either the seal or Solid Oil, whichever is lowest. If an induction heater is used, mounting temperatures of up to 120 °C (250 °F) are permissible.

## Speed limits

The limiting speeds for bearings and bearing units with Solid Oil are listed in **table 2** by the speed factor A.

As the frictional heat increases with speed, it might be necessary to limit the speed of a high-temperature application, so as not to exceed the Solid Oil temperature limit.

## Designation system

Refer to *Designation system* in the relevant product chapter of the standard bearing.

The designation suffixes used to identify SKF bearings with Solid Oil are explained in the following.

- W64** Synthetic base oil type, standard variant
- W64F** Synthetic base oil type, NSF H1 approved for food applications
- W64H** Synthetic base oil type, for slow speeds
- W64L** Synthetic base oil type, for low temperatures

Additional sealing suffixes used with SKF bearings with Solid Oil are explained in the following.

- Z** Shield on one side
- 2RS1** Contact seal, NBR, on both sides
- 2RSH** Contact seal, NBR, on both sides

## SKF DryLube bearings

SKF DryLube bearings are designed to reduce machine operating costs, extend maintenance intervals and provide a high degree of operational reliability, especially at extremely high temperatures. SKF DryLube bearings are filled with a dry lubricant, based on graphite and molybdenum disulfide ( $\text{MoS}_2$ ) and a resin binder. The dry lubricant is injected into the free space of the bearing and cured until it solidifies (→ **figs. 1** and **2**). The dry lubricant can protect the rolling elements and raceways from damage caused by solid contaminants.

During operation, the dry lubricant maintains a very thin film on the raceways and rolling elements to avoid metal-to-metal contact. After a while, small fragments of solid lubricant may break free and temporarily increase noise and vibration levels. This does not reduce the performance or service life of the bearing.

SKF DryLube bearings provide the following benefits:

- effective lubrication for high temperature applications
- low start-up torque at any temperature and low frictional moment during operation
- higher speed capabilities than bearings for extreme temperatures with a graphite cage
- lubricated for the life of the bearing
- minimal lubricant loss
- suitable for extremely slow rotating speeds and oscillating movements
- improved worker safety and environmentally friendly compared to many oils and greases

Typical applications where SKF DryLube bearings are used include:

- metals industry (rolls in bloom and billet casters, cooling and roll out tables, guide rolls in bar mills, reheating furnaces rolls)
- industrial ovens (kiln truck wheel bearings, roller hearth furnaces and chain bearings for hardening and annealing ovens)
- food and beverage industry (ovens, smoke-house conveyor lines, wafer machines, sterilization equipment)
- paint lines for automotive and powder coating
- paper industry (paper converting lines, rope sheaves)

### Assortment

Most SKF rolling bearings and bearing units can be supplied as SKF DryLube bearings provided the bearing is fitted with a sheet metal cage and is available with internal clearance greater than Normal.

The assortment of SKF DryLube bearings mentioned in this catalogue includes:

- deep groove ball bearings
- Y-bearings
- angular contact ball bearings
- cylindrical roller bearings
- tapered roller bearings
- spherical roller bearings
- thrust ball bearings
- spherical roller thrust bearings

For self-aligning ball bearings or customized units filled with dry lubricant, contact the SKF application engineering service.

For the assortment of deep groove ball bearings and Y-bearings with dry lubricant not described here, refer to *Bearings for extreme temperatures* (→ **page 1169**).

## Designs and variants

SKF DryLube bearings are available in three main variants to deliver superior performance, based on the operating conditions of the application (→ **table 1**). The bearings are filled with a dry lubricant based on graphite and molybdenum disulfide. To further increase speed capabilities or extend bearing service life, nano particles and perfluoro polyether (PFPE) oil additives are also available (→ **table 1**).

Deep groove ball bearings and Y-bearings in certain series and sizes are also available with manganese phosphate coated rings, rolling elements and cages to enhance adhesion of the dry lubricant to the metal and provide additional protection against corrosion (→ **fig. 2, page 1193**).

### WARNING

PFPE (perfluoro polyether) oil is very stable and harmless under normal operating conditions up to 250 °C (480 °F). However, if exposed to extreme temperatures above 300 °C (570 °F), PFPE oils give off hazardous fumes. These fumes can be harmful to the eyes and to the lungs, if inhaled.

The following safety precautions should be observed:

- Follow the safety precautions in the appropriate material safety data sheet (MSDS).
- If there is a risk of human exposure and the operating temperature is above 300 °C (570 °F), appropriate ventilation is required.

If the fumes have been inhaled, contact a doctor immediately.

The user is responsible for the correct use of the product during its service life and its proper disposal. SKF takes no responsibility for the improper handling of bearings with PFPE oil additives or for any injury resulting from their use.

## Selecting bearing size

The requisite bearing size for rotating bearings can be determined based on the basic dynamic load rating  $C$  (→ **product tables**).

The corresponding standard bearing should have a  $C$  value  $\geq$  the requisite value.

However, the basic static load rating  $C_0$  (→ **product tables**) is to be used when the bearings are to:

- rotate at very slow speeds ( $n < 10$  r/min)
- perform very slow oscillating movements
- be stationary under load for extended periods

The corresponding standard bearing should have a  $C_0$  value  $\geq$  the requisite value.

Calculating the requisite basic dynamic load rating	Calculating the requisite basic static load rating	Symbols
$C_{req} = S_{req} \frac{P}{f_T}$	$C_{0req} = 2 \frac{P_0}{f_T}$	$C_{req}$ = requisite basic dynamic load rating [kN]
To calculate $P$ , refer to the product chapter of the relevant standard bearing.	To calculate $P_0$ , refer to the product chapter of the relevant standard bearing.	$C_{0req}$ = requisite basic static load rating [kN]
$P < F_r \rightarrow P = F_r$	$P_0 < F_r \rightarrow P_0 = F_r$	$F_a$ = axial load [kN] $F_r$ = radial load [kN] $f_T$ = temperature factor (→ <b>table 3</b> )
For deep groove ball bearings, $F_a$ should not exceed $0,15 C_0$ .		$P$ = equivalent dynamic bearing load [kN] $P_0$ = equivalent static bearing load [kN] $S_{req}$ = guideline value for dynamic load safety factor (→ <b>table 4</b> )

200	390	0,9
250	480	0,75

## Temperature limits

The graphite-based lubricant in SKF DryLube bearings is effective at temperatures up to 500 °C (930 °F). At temperatures above 250 °C (480 °F), the resin binder begins to degrade, but the dry lubricant continues to lubricate. Therefore, for continuous operation at temperatures above 250 °C (480 °F), SKF recommends using bearings with a shield on both sides (designation suffix 2Z), or with a metal seal on both sides (→ **fig. 66, page 236**) to keep the lubricant in the bearing. Bearings with dry lubricant only between the inner ring (or the shaft washer) and cage (→ *Bearing data, page 1196*) may work at elevated temperatures without shields.

The recommended temperature limits are listed in **table 1** (→ **page 1195**).

## Speed limits

The limiting speed for the different variants of SKF DryLube bearings can be calculated using the formulae listed in **table 1** (→ **page 1195**).

**Diagram 4** provides estimated values. If the bearing clearance is greater than C3, the limiting speed should be reduced according to **diagrams 1 to 3** (→ **page 1199**).

## Design of bearing arrangements

SKF DryLube bearings for extreme temperatures can be mounted with a loose or an interference fit on the shaft and in the housing. However, either the inner or outer ring should be mounted with an interference fit, to locate the shaft and provide satisfactory support (→ **table 5**).

## Mounting

Mounting with mechanical force might crack the dry lubricant. Therefore, SKF DryLube bearings should always be hot mounted to reduce the mounting force.

For additional information, refer to *Mounting, dismantling and bearing care* (→ **page 271**) or the product chapter of the relevant standard bearing.

Diagram 4

Guidelines for limiting speeds of SKF DryLube radial ball bearings

## Maintenance

SKF DryLube bearings do not have a relubrication facility as they are lubricated for the life of the bearing.

## Designation system

Refer to *Designation system* in the relevant product chapter of the standard bearing.

The designation suffixes used to identify SKF DryLube bearings are part of group 4.6 (→ **diagram 3, page 44**) in the designation system. They are explained in the following.

- VA210** Graphite-based lubricant
- VA2101** Graphite-based lubricant and PFPE oil additive
- VA237** Graphite-based lubricant, PFPE oil additive and nano particles

## 15E INSOCOAT bearings

Electric motors, generators and associated equipment are at risk when an electric current passes through a bearing. This can damage the contact surfaces of rolling elements and raceways in the bearing (electrical erosion) and rapidly degrade the grease. An additional risk in electric motors and generators comes from high frequency currents due to the inherent stray capacitance. The risk of damage increases if the application uses a frequency converter.

INSOCOAT bearings (→ **fig. 1**) are designed to prevent current from passing through the bearing. The bearings are a very cost-effective solution compared with other insulation methods. By integrating the insulating properties into the bearing, INSOCOAT bearings can improve reliability and increase machine uptime by virtually eliminating the problem of electrical erosion.

### Designs and variants

An INSOCOAT bearing is a standard bearing that has the external surfaces of its inner or outer ring plasma-sprayed with an aluminium oxide to form a coating. The coating is sealed

with a resin to protect against the conductive effects of water and moisture.

The basic coating can withstand voltages up to 1 000 V DC. However, coatings to withstand voltages up to 2 000, or even 3 000 V DC, can be supplied on request.

The standard assortment of INSOCOAT bearings listed in this catalogue constitutes the most commonly used sizes and variants of:

- single row deep groove ball bearings
- single row cylindrical roller bearings

**Matrix 1** provides an overview of the standard assortment. For bearing types and sizes other than those listed, contact the SKF application engineering service.

For applications where smaller bearings than those listed are needed, SKF recommends using SKF hybrid bearings (→ *Hybrid bearings*, **page 1219**).

### INSOCOAT bearings with a coated outer ring

INSOCOAT bearings typically have the external surfaces of the outer ring coated with aluminium oxide. These bearings are identified by the designation suffix VL0241.

### INSOCOAT bearings with a coated inner ring

INSOCOAT bearings that have the external surfaces of the inner ring coated are identified by the designation suffix VL2071. These bearings provide enhanced protection against high frequency electric currents due to the smaller coated surface area of the inner ring compared to the outer ring.

## 15E INSOCOAT bearings

### Cages

INSOCOAT bearings are fitted with one of the following cages:

- for deep groove ball bearings
  - a stamped steel cage, riveted, ball centred (no designation suffix)
- for cylindrical roller bearings
  - a glass fibre reinforced PA66 cage, window-type, roller centred (designation suffix P)
  - a machined brass cage, riveted, roller centred (designation suffix M)
  - a machined brass cage, window-type, inner or outer ring centred, depending on the bearing design (designation suffix ML)

For additional information about cages, refer to *Cages* in the relevant product chapter (→ **page 298** for deep groove ball bearings and **page 582** for cylindrical roller bearings).

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

### Sealing solutions

Some INSOCOAT deep groove ball bearings can be supplied capped. For selection advice, contact the SKF application engineering service.

<b>Electrical properties</b>	The standard INSOCOAT layer provides protection against AC and DC currents. The minimum ohmic resistance is 50 MΩ at 1 000 V DC. Tests at SKF have shown that electrical breakdown of the insulating layer occurs above 3 000 V DC.	

## Loads

### Minimum load, axial load carrying capacity, equivalent dynamic bearing load, equivalent static bearing load

For load recommendations, refer to *Loads* in the relevant product chapter (→ **page 316** for deep groove ball bearings and **page 594** for cylindrical roller bearings).

## Temperature limits

Refer to *Temperature limits* in the relevant product chapter (→ **page 318** for deep groove ball bearings and **page 599** for cylindrical roller bearings).

## Permissible speed

Refer to *Permissible speed* in the relevant product chapter (→ **page 318** for deep groove ball bearings and **page 600** for cylindrical roller bearings).

## Design of bearing arrangements

### Abutment dimensions

To maximize the effectiveness of the insulation, SKF recommends the following guidelines for dimensioning the shaft and housing shoulders (→ **fig. 2**). For bearings with a coated outer ring (designation suffix VL0241), the abutment diameter in the housing should be  $\geq D_{a \min}$  (→ **product tables**). For bearings with a coated inner ring (designation suffix VL2071), the abutment diameter on the shaft should be  $\leq d_{a \max}$  (→ **product tables**).

### Mounting

During mounting, INSOCOAT bearings should be handled in the same way as standard bearings. When using an induction heater, the INSOCOAT layer must not be damaged by the vibration of the heater. For bearings with a coated inner ring (designation suffix VL2071), use a protective sleeve or an additional support block made of plastic.

In cases where springs are used to apply preload or lock nuts are used for axial clamping, SKF recommends inserting a steel spacer ring between the bearing and the preload or locking device (→ **fig. 3**).

## Designation system

Refer to *Designation system* in the relevant product chapter (→ **page 320** for deep groove ball bearings and **page 602** for cylindrical roller bearings).

The designation suffixes used to identify INSOCOAT bearings are explained in the following.

- VL0241** External surfaces of the outer ring are coated
- VL2071** External surfaces of the inner ring are coated

## Designs and variants

Hybrid bearings have rings made of bearing steel and rolling elements made of bearing grade silicon nitride ( $\text{Si}_3\text{N}_4$ ). Because the silicon nitride ceramic material is such an excellent electrical insulator, hybrid bearings can be used to effectively insulate the housing from the shaft in both AC and DC motors as well as in generators.

In addition to being an excellent insulator, hybrid bearings have higher speed capabilities and provide longer bearing service life under the same operating conditions than same-sized all-steel bearings. Hybrid bearings also perform extremely well under vibrating or oscillating conditions. Often, it is not necessary to preload the bearing or apply a special grease under these conditions.

### Factors that influence SKF hybrid bearing performance

Bearing performance is not only determined by load or speed ratings. There are a number of other factors that contribute to bearing performance. Main factors that enhance SKF hybrid bearing performance, when compared to same-sized all-steel bearings, include:

- **Insulating properties**

As a non-conductive material, silicon nitride protects the rings from electric current damage and, therefore, can extend bearing service life in applications like AC and DC motors and generators, where there are electric currents that could damage the bearing.

- **Lower density**

The density of a bearing grade silicon nitride rolling element is 60% lower than a same-sized rolling element made of bearing steel. Lower weight means lower inertia – and that translates into superior behaviour during rapid starts and stops, as well as higher speed capabilities.

- **Lower friction**

The lower density of a silicon nitride rolling element, combined with its low coefficient of friction, significantly reduces bearing temperature at high speeds. Cooler running extends the service life of both the bearing and the lubricant.

- **High hardness and high modulus of elasticity**

The high degree of hardness of a silicon nitride rolling element means high wear-resistance, increased bearing stiffness and longer bearing service life in contaminated environments.

- **Resists false brinelling**

If a stationary bearing is subjected to vibrations, there is a risk that “false brinelling” occurs. False brinelling is the formation of shallow depressions in the raceways that eventually lead to spalling and premature bearing failure. In cases where steel rolling elements were replaced by ceramic rolling elements, the bearings were found to be significantly less susceptible to false brinelling.

Hybrid bearings lubricated with SKF wide temperature grease (WT) were found to sustain less false brinelling damage than hybrid bearings lubricated with other types of greases.

- **Reduced risk of smearing between silicon nitride and steel surfaces**

Even under inadequate lubrication conditions, there is reduced risk of smearing between silicon nitride and steel surfaces. This enables hybrid bearings to operate much longer in applications where there are high speeds and fast accelerations, or applications where there is an insufficient hydrodynamic film to support undisturbed bearing operation (i.e.  $\kappa < 1$ , → *Selecting bearing size*, **page 61**). For conditions where  $\kappa < 1$ , it is common to apply  $\kappa = 1$  for hybrid bearings for bearing life calculations. Hybrid bearings may perform well when lubricated with ultra-thin film forming media, such as refrigerants, typically used in compressor applications or fuel pumps, enabling oil-free designs.

- **Runs faster, lasts longer**

Combine the lower density of silicon nitride with its lower coefficient of friction, high hardness and the fact that silicon nitride does not smear the raceways under poor lubrication conditions, and the result is a bearing that runs faster and longer even under the most difficult operating conditions.

- **Low coefficient of thermal expansion**

A silicon nitride rolling element has a lower coefficient of thermal expansion than a same-sized rolling element made of bearing steel. This means less sensitivity to temperature gradients within the bearing and more accurate preload/clearance control.

When designing bearing arrangements for very low temperatures, a hybrid bearing with greater internal clearance than standard may need to be selected. In these cases, contact the SKF application engineering service.

- **Speed capability**

Typically, hybrid bearings have a higher speed capability than same-sized all-steel bearings, however, in some cases, the cage execution may limit the attainable speed.

### Assortment

The assortment of SKF hybrid bearings listed in this catalogue comprises popular sizes for electric motors and generators (→ **matrix 1**). It includes:

- single row deep groove ball bearings
  - basic design
  - sealed design
  - XL hybrid design
- single row cylindrical roller bearings

Hybrid bearings listed in this catalogue constitute the basic SKF assortment and are only part of the total assortment. Other hybrid bearings include:

- Hybrid super-precision bearings (→ [skf.com/super-precision](http://skf.com/super-precision))
  - hybrid super-precision angular contact ball bearings
  - hybrid super-precision cylindrical roller bearings
  - hybrid super-precision angular contact thrust ball bearings, single and double direction
- Hybrid angular contact ball bearings
- Hybrid stainless steel deep groove ball bearings
- Bearing units incorporating hybrid bearings

## Hybrid deep groove ball bearings

Deep groove ball bearings are the most widely used bearing type, especially in electric motors. These non-separable bearings are suitable for high speeds. The deep uninterrupted raceway grooves have a close osculation with the balls, enabling the bearings to accommodate radial loads and axial loads in both directions.

SKF hybrid deep groove ball bearings are available with a bore diameter ranging from 5 to 180 mm. They are manufactured to SKF Explorer performance class quality.

Bearings with a bore diameter  $d \leq 45$  mm are most suitable for electric motors in the power range of 0,15 up to 15 kW as well as power tools and high-speed drives. SKF hybrid deep groove ball bearings in this size range are the most cost-effective solution against electrical erosion.

### Basic design bearings

Basic design bearings are available with a bore diameter  $d > 45$  mm (→ **fig. 1**). If a small quantity of smaller open design bearings is required, SKF recommends ordering sealed hybrid bearings and removing the seals.

Fig. 1

## Sealing solutions

Sealed hybrid deep groove ball bearings use the same seals as described in the relevant section of *Deep groove ball bearings* (→ **page 295**). They are lubricated for the life of the bearing and should not be washed or relubricated. The bearings are considered maintenance-free. If they are to be hot mounted, SKF recommends using an induction heater whenever possible. SKF does not recommend heating a sealed bearing above 80 °C (175 °F).

### Greases for sealed bearings

Sealed hybrid deep groove ball bearings are filled with a high-quality grease under clean conditions. The standard grease, suitable for the most common operating conditions of electric motors and generators, is indicated by the designation suffix WT. Grease specifications are listed in **table 4** (→ **page 305**), under grease "WT".

For additional information about greases, refer to *Lubrication* (→ **page 239**).

### Grease life

For SKF hybrid deep groove ball bearings, the estimated grease life can be assumed to be at least twice as long as for same-sized all-steel bearings (→ *Grease life for capped bearings*, **page 306**). Conditions such as the presence of water or other fluids or vibration can reduce the grease life.

## XL hybrid bearings

XL hybrid deep groove ball bearings (designation suffix VA970) are designed to meet the application requirements for electric generators in larger wind turbines. SKF supplies XL hybrid deep groove ball bearings for the most commonly used generator sizes (→ **product table**).

### WARNING

Seals made of FKM (fluoro rubber) exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions under *Seal materials* (→ **page 155**).

## 15F Hybrid bearings

### Hybrid cylindrical roller bearings

Hybrid cylindrical roller bearings are commonly used in electric motors, especially traction motors, and in applications running under severe operating conditions. They can accommodate heavy radial loads and high speeds.

The NU design cylindrical roller bearing, which has two integral flanges on the outer ring and no flanges on the inner ring, is the standard variant for hybrid cylindrical roller bearings (→ **fig. 2**).

Fig. 2

## Cages

Depending on their size, SKF hybrid deep groove ball bearings are fitted with one of the following cages:

- a stamped steel cage, riveted, ball centred (no designation suffix)
- a glass fibre reinforced PA66 cage, snap-type, ball centred (designation suffix TN9)
- a glass fibre reinforced PEEK cage, snap-type, ball centred (designation suffix TNH)

Depending on their series and size, SKF hybrid cylindrical roller bearings are fitted with one of the following cages:

- a glass fibre reinforced PA66 cage, window-type, roller centred (designation suffix P)
- a glass fibre reinforced PEEK cage, window-type, roller centred (designation suffix PH)
- a machined brass cage, riveted, roller centred (designation suffix M)
- a machined brass cage, window-type, inner or outer ring centred, depending on the bearing design (designation suffix ML)

For additional information about cages, refer to *Cages* in the relevant product chapter (→ **page 298** for deep groove ball bearings and **page 582** for cylindrical roller bearings).

The lubricants generally used for rolling bearings do not have a detrimental effect on cage properties. However, some synthetic oils and greases with a synthetic oil base and lubricants containing a high proportion of EP additives, when used at high temperatures, can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages* (→ **page 37**) and *Cage materials* (→ **page 152**).

## Hybrid bearings with special steel rings and coatings

Hybrid bearings can be customized for specific application requirements. For additional information about the following variants, contact the SKF application engineering service.

- bearing rings stabilized for temperatures  $\leq 300\text{ °C}$  ( $570\text{ °F}$ )
- bearing rings made of through-hardened stainless steel for enhanced corrosion and wear-resistance and with good high-temperature properties
- bearing rings made of through-hardened stainless steel for cryogenic temperatures
- bearing rings made of high-temperature tool steel
- coating with zinc chromate or thin dense chromium for corrosion protection
- coating based on molybdenum for low friction, especially in vacuum or gas applications

<b>Axial displacement</b>	–	NU design hybrid cylindrical roller bearings can accommodate axial displacement of the shaft relative to the housing within the bearing. Values for the permissible axial displacement $s$ from the normal position of one bearing ring relative to the other are listed in the product tables.
<b>Defect frequencies</b>	Defect frequencies can be calculated using the tools available online at <a href="http://skf.com/bearingcalculator">skf.com/bearingcalculator</a> .	
<b>Silicon nitride properties</b>	For bearing grade silicon nitride ( $\text{Si}_3\text{N}_4$ ), refer to <i>Materials for rolling bearings</i> (→ page 150).	
<b>Electrical properties</b>	Hybrid bearings provide protection against AC and DC currents. The impedance for a hybrid bearing is high, even for very high frequencies, providing good protection against high frequency current and voltage peaks. For small hybrid deep groove ball bearings fitted with a contact NBR seal, the voltage level before the first arcing occurs through the seal/bearing contact is > 2,5 kV DC. For additional information, contact the SKF application engineering service.

### Temperature limits

The permissible operating temperature for hybrid bearings can be limited by:

- the dimensional stability of the bearing rings
- the cage
- the seals
- the lubricant

When temperatures outside the permissible range are expected, contact the SKF application engineering service.

#### Bearing rings

The rings of SKF hybrid bearings undergo a special heat treatment. Depending on the bearing type and variant, hybrid bearings are heat stabilized up to:

- 120 °C (250 °F) for hybrid deep groove ball bearings
- 150 °C (300 °F) for hybrid cylindrical roller bearings and XL hybrid deep groove ball bearings

On request, SKF can supply hybrid bearings with rings stabilized for operating temperatures up to 300 °C (570 °F).

#### Cages

Steel, brass or PEEK cages can be used at the same operating temperatures as the bearing rings of standard hybrid bearings. For temperature limits of other polymer cages, refer to *Cage materials* (→ page 152).

#### Seals

The permissible operating temperature for seals depends on the material:

- NBR seals:  
–40 to +100 °C (–40 to +210 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- FKM seals:  
–30 to +230 °C (–20 to +445 °F)

#### Lubricants

Temperature limits for the grease used in sealed SKF hybrid deep groove ball bearings are provided under *Deep groove ball bearings*

(→ table 4, page 305). Temperature limits for other SKF greases are provided under *Lubrication* (→ page 239).

When using lubricants not supplied by SKF, the temperature limits should be evaluated according to the SKF traffic light concept (→ page 244).

### Permissible speed

The permissible speed can be estimated using the speed ratings listed in the product tables and applying the information provided under *Speeds* (→ page 117). If no reference speed is listed in the product tables, the limiting speed is the permissible speed.

The values for the reference speed listed in the product tables for sealed deep groove ball bearings are valid for basic design bearings (i.e. seals removed from the bearings) and demonstrate the speed capability of these bearings.

### Designation system

Refer to *Designation system* in the relevant product chapter (→ page 320 for deep groove ball bearings and page 602 for cylindrical roller bearings).

Additional designation suffixes used with SKF hybrid bearings are explained in the following.

<b>HC5</b>	Rolling elements made of silicon nitride
<b>VA970</b>	Special design for wind turbine generators
<b>-2RSH2</b>	Contact seal, FKM, on both sides
<b>C3P</b>	Displaced clearance range comprising the upper half of the C3 plus the lower half of the C4 clearance range
<b>F1</b>	Grease fill 10–15% of the free space in the bearing
<b>S0</b>	Bearing rings heat stabilized for operating temperatures ≤ 150 °C (300 °F)

## NoWear coating

NoWear is a wear-resistant carbon coating that can be applied to the rolling elements and inner ring raceway(s) of a bearing (designation suffix L7DA) or only the rolling elements (designation suffix L5DA) (→ **fig. 1**). A physical vapour deposition process applies the wear-resistant carbon coating ranging from 1 to 3 µm depending on the size of the bearing. The hardness of the coating is 1 200 HV10.

NoWear coated bearing surfaces retain the toughness of the underlying material while adopting the hardness, improved friction properties and wear-resistance of the coating.

During the running-in period, minute amounts of the coating material are transferred to the counter surfaces. This transfer reduces friction and improves resistance against wear and smearing, even in bearings where only the rolling elements are coated.

NoWear coated bearings are designed to extend service life, relubrication intervals and to withstand severe operating conditions including:

- increased risk of smearing
- insufficient lubricating film for undisturbed bearing operation ( $\kappa < 1$ )
- sudden load variations
- light loads
- rapid speed changes
- vibration and oscillations
- high operating temperatures

NoWear coated bearings open up new possibilities to existing applications operating under severe conditions. They do not require major design changes and provide new design possibilities. Typical applications where NoWear coated bearings are used include:

- paper machines
- marine and offshore
- fans
- compressors
- hydraulic pumps
- gearboxes
- motors

For demanding applications where NoWear coated bearings are being considered, several operating parameters must be taken into consideration and weighed against each other. Therefore, SKF recommends contacting the SKF application engineering service prior to selecting NoWear coated bearings.

NoWear coated bearings are not intended for vacuum or other completely dry running applications. The coating does not act as a barrier against oxygen and is therefore not recommended as a corrosion inhibitor.

#### **Bearing service life**

The extended bearing service life that NoWear can provide in high-speed, lightly loaded applications is difficult to calculate and depends on a variety of factors. However, experience has shown a multifold improvement in bearing service life.

For greased bearings that operate at speeds near or above the permissible speed, or at high temperatures that shorten the grease life, using NoWear extends relubrication intervals.

When the objective is to extend bearing service life in applications with heavy loads and marginal lubrication conditions, NoWear can be a solution. However, NoWear cannot protect the bearing against spalling as a result of constant heavy loads. Under heavy loads the maximum shear stresses are located below the coating within the bearing steel, which still has the properties of standard steel.

## Designs and variants

The most commonly used NoWear coated bearings have only the rolling elements coated (designation suffix L5DA). They are recommended for applications where the bearing load is light to normal, or where vibration and oscillating movements occur.

NoWear coated bearings that have the inner ring raceway(s) and rolling elements coated (designation suffix L7DA) are recommended for any of the following operating conditions:

- abrasive contaminants that can cause premature wear
- heavy loads
- unusual lubrication conditions such as bearings lubricated by the process media

Most SKF rolling bearings can be supplied as NoWear coated bearings (→ **table 1**). For other variants, contact the SKF application engineering service.

## Cages

Refer to *Cages* in the relevant product chapter of the standard bearing.

## Bearing data

### Dimension standards, tolerances, internal clearance, misalignment, defect frequencies

Refer to *Bearing data* in the relevant product chapter of the standard bearing.

## Loads

### Minimum load

Due to the material combination of NoWear/ steel in the contact area, the risk of smearing damage is reduced. NoWear coated bearings are recommended for applications with light loads in combination with high speeds.

## Load carrying capacity, equivalent loads

Refer to *Loads* in the relevant product chapter of the standard bearing.

## Temperature limits

The wear-resistant carbon coating withstands temperatures of up to 350 °C (660 °F). For temperature limits of the bearing, refer to *Temperature limits* in the relevant product chapter of the standard bearing.

## Permissible speed

Refer to *Permissible speed* in the relevant product chapter of the standard bearing.

## Lubrication

In general, the same lubrication guidelines are valid for NoWear coated bearings as for standard bearings (→ *Lubrication*, **page 239**). However, NoWear coated bearings can operate reliably even when adequate surface separation cannot be achieved by the lubricant ( $\kappa < 1$ ). NoWear can prevent direct metal-to-metal contact between the rolling elements and raceways. It might be possible to reduce the need for EP and AW additives in the lubricant when using a NoWear coated bearing, as the coating already acts as a powerful additive.

## Designation system

Refer to *Designation system* in the relevant product chapter of the standard bearing.

The designation suffixes used to identify NoWear coated bearings are explained in the following.

## 15H Polymer ball bearings

SKF polymer ball bearings are typically used in applications where resistance to moisture or chemicals is essential and all-steel bearings cannot be used or only with certain restrictions. In those applications, polymer ball bearings are an excellent solution from both a technical and economic perspective as they are characterized by the following properties:

- corrosion and chemical resistant
- high wear- and fatigue-resistant polymer
- self lubricating (no lubricant required)
- low coefficient of friction
- quiet running
- lightweight
- high specific strength (strength to weight ratio)
- high dimensional stability due to the low tendency to creep
- low lifecycle costs
- electrical insulator

These properties make polymer ball bearings appropriate for the following industries and applications:

- food and beverage industry
- medical and pharmaceutical industry
- chemical industry
- textile industry
- electrical industry
- photographic industry
- modelling and lightweight applications
- vacuum applications
- office products

## Designs and variants

The standard assortment of SKF polymer ball bearings listed in this catalogue constitutes the most commonly used sizes of:

- single row deep groove ball bearings (→ **fig. 1**)
- thrust ball bearings (→ **fig. 2**)

Both bearing designs have uninterrupted raceways and are non-separable. Standard bearings are only available as open bearings (without seals or shields).

On request, other polymer bearings or units are available (→ **fig. 3**). Customized polymer bearings can be manufactured economically even in small quantities. Integrated functions (e.g. gearing, specific shape of the bore, etc.) that can reduce the number of components and assembly costs are also possible. Examples of those bearings, which are not listed in this catalogue, include:

- inch single row deep groove ball bearings
- full complement single row deep groove ball bearings
- sealed single row deep groove ball bearings
- double row deep groove ball bearings
- track runner bearings
- Y-bearings and Y-bearing units
- special size bearings
- bearings or components made of other materials
- bearing units with integrated functions

**NOTE:** Polymer ball bearings cannot accommodate the same heavy loads or high speeds as same-sized all-steel bearings.

Fig. 1

### Single row deep groove ball bearings

SKF supplies standard single row deep groove ball bearings in various dimension series for shaft diameters ranging from 3 to 60 mm. They consist of:

- polymer rings
- balls made of stainless steel or glass
- a polymer cage

### Thrust ball bearings

SKF supplies standard thrust ball bearings in various dimension series for shaft diameters ranging from 10 to 45 mm. Thrust ball bearings consist of polymer washers and a full complement ball set. The ball set per bearing consists of two different ball materials to reduce friction and frictional heat. Balls made of the selected material are fitted alternately with balls made of the same polymer as the washers.

Fig. 2

### Cages

Single row deep groove ball bearings are fitted with a snap-type, ball centred polymer cage (→ fig. 4).

Thrust ball bearings have a full complement ball set and do not have a cage.

### Materials

SKF polymer ball bearings can be manufactured from a variety of materials and material combinations. The selected materials depend on the application conditions. Polymer ball bearings are available in the four standard material combinations listed in **table 1** for single row deep groove ball bearings and in **table 2** for thrust ball bearings. A four-digit combination designation suffix (→ *Designation system*, **page 1260**) identifies the selected materials.

### Chemical resistance

Most polymers can resist the damaging effects of commonly used chemicals.

Polypropylene (PP) resists acids, alkalis, salts and salt solutions, alcohols, oils, greases, waxes and many solvents. However, exposure to aromatic compounds and halogenated hydrocarbons cause the material to swell. PP also does not resist strong oxidizing media like nitric acid, chromates or halogens.

Polyoxymethylene (POM) resists weak acids, weak and strong alkalis and organic solvents as well as gasoline, benzene, oils and alcohols.

Polyamide 66 (PA66) resists almost all organic solvents as well as some weak acids and alkalis.

**Table 3** provides an overview of the chemical resistance of available materials to common substances.

For additional information, refer to *Factors influencing bearing performance* (→ page 1259).

## Loads

There are no standardized calculation methods, either nationally or internationally, to calculate basic load ratings for polymer ball bearings. According to the current state of technology, an analytical life calculation is not possible.

For slow speeds ( $n < 25$  r/min), the static load carrying capacity is to be used.

<p><b>Dynamic load carrying capacity</b></p>	<p>The dynamic load carrying capacity is an indicator for the operational load at which the bearing fulfils its function in the majority of applications. The dynamic load carrying capacity depends on the operating conditions and needs to be adjusted under the following conditions:</p> <ul style="list-style-type: none"> <li>• operating temperature <math>T &gt; 50</math> °C (120 °F)</li> <li>• rotational speed <math>n \geq 20\%</math> of the limiting speed <math>n_{lim}</math> (→ <b>product tables</b>)</li> </ul> $C_{adj} = f_T f_n C$ <p><b>Calculation example</b> Bearing 6301/HR11TN, <math>n = 650</math> r/min, <math>T = 90</math> °C (195 °F)</p> <p>From the product tables:</p> <ul style="list-style-type: none"> <li>• <math>C = 0,31</math> kN</li> <li>• <math>n_{lim} = 1\,300</math> r/min</li> </ul> <p>From <b>diagram 1, page 1256</b>:</p> <ul style="list-style-type: none"> <li>• with <math>T = 90</math> °C (195 °F) and rings made of POM → <math>f_T \approx 0,87</math></li> <li>• with <math>n/n_{lim}: (650/1\,300) \times 100 = 50\%</math> → <math>f_n \approx 0,85</math></li> </ul> $C_{adj} = 0,87 \times 0,85 \times 0,31 = 0,229$ kN
<p><b>Static load carrying capacity</b></p>	<p>The static load carrying capacity is the maximum load that a bearing can accommodate at standstill without sustaining damage to the balls or raceways.</p> <p>The static load carrying capacity depends on the operating temperature and should be adjusted at operating temperatures <math>T &gt; 50</math> °C (120 °F).</p> $C_{0adj} = f_T C_0$

<sup>1)</sup> For speeds below 25 r/min, the static load carrying capacity is to be used.

## Temperature limits and thermal expansion

The permissible operating temperature for polymer ball bearings is limited by the type of polymer. **Diagram 2** provides a summary of the operating temperatures for polymer materials. When temperatures outside the permissible range or below 0 °C (30 °F) are expected, contact the SKF application engineering service.

In combination with the operating temperature, thermal expansion is also important. The coefficient of thermal expansion (→ **diagram 3**) enables designers to predict the effects that temperature has on bearing internal clearance. The coefficient of thermal expansion for a polymer can be up to 10 times greater than for steel. Even the coefficient of thermal expansion for different polymers can vary considerably. Therefore, thermal expansion can have a significant influence on bearing internal clearance and should be considered when selecting shaft and housing fits (→ *Shaft and housing fits*, page 1259) and when selecting the bearing materials.

Diagram 2

Operating temperature range for polymers

Diagram 3

Coefficient of thermal expansion  $\alpha$

## Permissible speed

For polymer ball bearings, the limiting speed (→ **product tables**) is to be used as the determining factor to estimate the permissible speed.

The permissible speed depends on the applied load and the operating temperature. When both values are known, the adjustment factor for speed  $f_n$  is to be calculated using

$$f_n = \frac{P}{f_T C}$$

where

$f_n$  = adjustment factor for speed

$P$  = applied bearing load [kN]

$f_T$  = adjustment factor for temperature  
(→ **diagram 1, page 1256**)

$C$  = basic dynamic load rating [kN]  
(→ **product tables**)

Starting with the calculated adjustment factor for speed  $f_n$  from the y-axis (→ **diagram 1, page 1256**), the percentage of the limiting speed can be determined and the permissible speed can be calculated.

## Calculation example

- **Input data**

Bearing 6301/HR11TN,  $P = 0,245$  kN,  
 $T = 90$  °C (195 °F)

- **Calculate the adjustment factor for speed  $f_n$**

From the **product tables**:

$C = 0,31$  kN

From **diagram 1, page 1256**:

With  $T = 90$  °C (195 °F) and rings made of POM →  $f_T \approx 0,87$

$$f_n = \frac{0,245}{0,87 \times 0,31} \approx 0,91$$

- **Calculate the permissible speed**

From the **product tables**:

$n_{lim} = 1\,300$  r/min

From **diagram 1, page 1256**:

With  $f_n = 0,91$  and rings made of POM the percentage of  $n_{lim} \approx 40\%$

$$n_{perm} = \frac{n_{lim} \times 40}{100} = \frac{1\,300 \times 40}{100} \approx 520 \text{ r/min}$$

where

$n_{perm}$  = permissible speed [r/min]

$n_{lim}$  = limiting speed [r/min]  
(→ **product tables**)

## Design of bearing arrangements

### Shaft and housing fits

Shaft and housing fits can have a significant influence on the internal clearance and the operating characteristics of polymer ball bearings. Therefore, SKF recommends approximately 20 µm interference fit for one ring only. Depending on the application, the interference fit can be on the shaft or in the housing. The other ring should have a loose fit.

Never subject both bearing rings to an interference fit as it preloads the bearing, causing it to fail prematurely.

These recommendations are only guidelines to calculate a fit. Thermal expansion of the bearing components under operating conditions must be taken into consideration.

For additional information, contact the SKF application engineering service.

## Factors influencing bearing performance

In many applications, the performance of polymer ball bearings is influenced by factors (temperature, pressure, material tension, interaction with chemical substances, design features etc.) that are difficult to replicate in laboratory tests or to be considered by adjustment factors. Because of the complexity of these effects on these bearings, the information provided in this chapter should be used as a guideline and cannot substitute for field testing a selected polymer ball bearing in its specific application. Therefore, SKF recommends field testing a selected polymer ball bearing to make sure that it performs satisfactorily within the application.

For additional information, contact the SKF application engineering service.

## 15H Polymer ball bearings

### Designation system

#### Basic designation

Listed in **diagram 2** (→ **page 43**)

#### Suffixes

#### Cage design

**V** Full complement of balls (no cage)

#### Materials

**HR** Polymer ball bearings

#### Material combination designation

**Character 1** Outer ring

**Character 2** Inner ring

**Character 3** Balls

**Character 4** Cage (single row deep groove ball bearings)

Alternate balls (thrust ball bearings)

#### Material codes:

<b>1</b>	Polyoxymethylene (POM)
<b>2</b>	Polypropylene (PP)
<b>3</b>	Polyethylene (PE)
<b>6</b>	Polyetheretherketone (PEEK)
<b>8</b>	Polyoxymethylene sooted (POM sooted)
<b>B</b>	Polyethylene terephthalate (PET)
<b>D</b>	Ceramic ZrO <sub>2</sub>
<b>K</b>	Polyvinylidene fluoride (PVDF)
<b>L</b>	Polyphenylensulfide (PPS)
<b>M</b>	Polyimide (PI)
<b>N</b>	Polyamide 66 (PA66)
<b>P</b>	Brass
<b>Q</b>	Glass
<b>R</b>	Borosilicate glass
<b>S</b>	Stainless steel 1.4034
<b>T</b>	Stainless steel 1.4401
<b>W</b>	Titanium
<b>X</b>	Ceramic Si <sub>3</sub> N <sub>4</sub>
<b>Z</b>	Ceramic Al <sub>2</sub> O <sub>3</sub>

The complete designation is printed on the package. Polymer ball bearings do not have the designation inscribed on the rings or washers.

## Adapter sleeves

Adapter sleeves are the most commonly used components for locating bearings with a tapered bore onto a cylindrical seat as they can be used on plain or stepped shafts (→ **fig. 1**). They are easy to install and require no additional location on the shaft. When adapter sleeves are used on plain shafts, the bearing can be located at any position on the shaft. When used on stepped shafts together with an L-shaped spacer ring, bearings can be accurately positioned axially thereby facilitating bearing mounting and dismounting.

### Designs and variants

#### Basic design

SKF supplies metric adapter sleeves with a metric or an inch bore and inch adapter sleeves. The sleeves are slit and supplied complete with a lock nut and locking device. Smaller sizes use a nut and a lock washer. Larger sizes use a nut and a locking clip or locking plate (→ **fig. 2**).

Metric sleeves with a bore diameter  $\leq 180$  mm (size  $\leq 40$ ) are phosphated. Larger metric sleeves and all inch sleeves are coated with a solventless rust inhibitor.

Adapter sleeves listed in this catalogue constitute the basic SKF assortment and are only part of the total assortment. For larger sizes (bore diameter  $\geq 1\ 060$  mm) and variants not listed in the product tables, contact SKF.

#### Variants for oil injection

Adapter sleeves with oil supply ducts and distribution grooves are available to enable use of the oil injection method to mount and dismount bearings (OH, OSNW and OSNP series, → **figs. 3 to 6, pages 1271 and 1272**).

Thread details for the oil supply ducts and the appropriate hydraulic nut designations are listed in the product tables. For information about oil injection equipment, refer to the catalogue *SKF Maintenance and Lubrication Products* or visit [skf.com/mapro](http://skf.com/mapro).

Fig. 2

Metric sleeves with a bore diameter  $\geq 200$  mm (size  $\geq 44$ ) are equipped with the necessary ducts and grooves as standard. For metric sleeves with a bore diameter  $\geq 140$  mm (size  $\geq 32$ ) and inch sleeves with a bore diameter  $\geq 4 \frac{5}{16}$  in. (size  $\geq 26$ ), these features are available on request.

SKF manufactures oil injection sleeves in four variants that differ in the number and arrangement of the oil supply ducts and distribution grooves:

- designation suffix H (→ fig. 3)  
These are the SKF standard adapter sleeves for oil injection. These sleeves have an oil supply duct at the threaded end of the sleeve and a distribution groove on the outside surface.
- no designation suffix (→ fig. 4)  
These sleeves have an oil supply duct at the end opposite the threaded section and a distribution groove on the outside surface.

Fig. 3

Fig. 4

## 16 Bearing accessories

- designation suffix B (→ **fig. 5**)  
These sleeves have one or two oil supply ducts at the end opposite the threaded section and a distribution groove in the bore and on the outside surface. Metric and inch sleeves with a bore diameter < 200 mm (size ≤ 40) have one supply duct. Larger metric sleeves have two. Larger inch sleeves are made to order and can be supplied with one or two supply ducts on request. When sleeves have two supply ducts, each duct feeds one of the distribution grooves. An arrow on the sleeve side face, next to the duct inlet, indicates which groove the duct feeds.
- designation suffix HB (→ **fig. 6**)  
These sleeves have one or two oil supply ducts at the threaded end of the sleeve and a distribution groove in the bore and on the outside surface. Metric and inch sleeves with a bore diameter < 200 mm (size ≤ 40) have one supply duct. Larger metric sleeves have two. Larger inch sleeves are made to order and can be supplied with one or two supply ducts on request. When sleeves have two supply ducts, each duct feeds one of the distribution grooves. ### Variants for CARB toroidal roller bearings

Modified adapter sleeve assemblies with designation suffixes E, L and TL (→ **fig. 7**) are typically available for CARB bearings to prevent the locking device from interfering with the cage:

- Sleeves with a designation suffix E
  - The standard KM lock nut and MB lock washer are replaced with a KMFE lock nut.
  - The standard HM 30 or HM 31 lock nut is replaced with an HME lock nut.
- Sleeves with a designation suffix L
  - The standard KM lock nut and MB lock washer are replaced with a KML lock nut and MBL lock washer because both have a lower sectional height.
- Sleeves with a designation suffix TL
  - The standard HM .. T lock nut and MB lock washer are replaced with an HM 30 lock nut and an MS 30 locking clip because both have a lower sectional height.

When using CARB bearings on an adapter sleeve, check that there is sufficient space between the locking device and bearing to accommodate axial displacement (→ *Axial displacement*, **page 968**).

### Variants for sealed bearings

Modified adapter sleeve assemblies with designation suffixes E, EL, EH, L and TL are typically available for sealed spherical roller bearings and sealed self-aligning ball bearings to prevent the locking device from interfering with the seal (→ **fig. 7** for designation suffixes E, L and TL). Adapter sleeve assemblies with a designation suffix EL or EH use either a KMFE .. L lock nut, which has a lower abutment diameter than the standard KMFE lock nut (→ **fig. 8**), or a KMFE .. H lock nut (→ **fig. 8**), which has a higher abutment diameter than the standard KMFE lock nut.

<b>Shaft tolerances</b>	h9Ⓜ Cylindricity: IT5/2 – ISO 1101 Adapter sleeves adapt to the shaft diameter, so that wider diameter tolerances can be permitted compared to the seat of a bearing with a cylindrical bore. However, the form tolerances must be kept within narrow limits as the accuracy of form directly affects the running accuracy of the bearing.	

## Withdrawal sleeves

Withdrawal sleeves can be used to mount bearings with a tapered bore on the cylindrical seat of stepped shafts (→ **fig. 9**). The sleeve is pressed into the bore of the bearing inner ring, which abuts a shaft shoulder or similar fixed component. The sleeve is located on the shaft by a nut or an end plate. Lock nuts or end plates are not supplied with withdrawal sleeves. KM or HM lock nuts (→ **page 1278**) with appropriate locking devices are suitable, but must be ordered separately.

To press the withdrawal sleeve into the bearing bore, a considerable amount of force is required to overcome the friction between the bearing, sleeve and shaft. To facilitate mounting and dismounting bearings on withdrawal sleeves, SKF recommends using a hydraulic nut (→ **fig. 10**).

Fig. 9

Fig. 10

## 16 Bearing accessories

### Designs and variants

#### Basic design

SKF withdrawal sleeves (→ **fig. 11**) are slit. Sleeves with a bore diameter  $\leq 190$  mm (size  $\leq 40$ ) are phosphated. Larger sleeves are coated with a solventless rust inhibitor.

The nut required to dismount a withdrawal sleeve must be ordered separately. Appropriate sizes of nuts are listed in the product tables.

Withdrawal sleeves listed in this catalogue constitute the basic SKF assortment. For larger sizes (bore diameter  $\geq 1\,060$  mm), contact SKF.

#### Variant for oil injection

Withdrawal sleeves with oil supply ducts and distribution grooves, which enable use of the oil injection method to mount and dismount bearings (AOH series, → **fig. 12**), are available. These sleeves have two oil supply ducts at the threaded end that feed the distribution grooves. The distribution grooves are in the circumferential and axial directions, on both the outside surface and the sleeve bore. Thread details for the oil supply ducts are listed in the product tables.

SKF withdrawal sleeves with a bore diameter  $\geq 200$  mm (size  $\geq 44$ ) are equipped with the necessary ducts and grooves as standard. For sleeves with a bore diameter  $\geq 150$  mm (size  $\geq 32$ ), these features are available on request.

For information about oil injection equipment, refer to the catalogue *SKF Maintenance and Lubrication Products* or visit [skf.com/mapro](http://skf.com/mapro).

## Lock nuts

Lock nuts are used to locate bearings and other components onto a shaft or adapter sleeve. They are also used for mounting bearings on tapered shaft seats and dismantling bearings from withdrawal sleeves. Lock nuts have to be secured to prevent unintentional loosening. This is done, either by a locking device that engages a keyway in the shaft or key slot in the adapter sleeve, or by a locking mechanism integrated in the nut. Lock nuts with an integrated locking mechanism reduce the cost of the shaft as no keyway is required. Installation is also quicker and easier because no separate locking device is necessary. However, the loosening torque of these lock nuts requires more attention (→ [page 1284](#)).

### Designs and variants

SKF lock nuts provide a variety of ways to secure the nut onto the shaft. The lock nuts listed in this catalogue constitute the basic SKF assortment. Lock nuts with other locking methods can be supplied on request. For additional information, contact the SKF application engineering service.

#### Lock nuts with a lock washer, locking clip or locking plate

These lock nuts are available in different series (→ [fig. 13](#)):

- KM and KML lock nuts have metric threads and use lock washers (→ [fig. 14](#)).
- HM .. T lock nuts have metric trapezoidal threads and use lock washers (→ [fig. 14](#)). For some sizes no lock washer is available, because these nuts are intended only for removal purposes.
- HM and HME lock nuts have metric trapezoidal threads and use locking clips (→ [fig. 15](#)).
- N and AN lock nuts have inch dimensions. Thread diameters  $\leq 8 \frac{5}{8}$  in. (size  $\leq 44$ ) use a lock washer (→ [fig. 14](#)). Thread diameters  $\geq 9 \frac{7}{16}$  in. (size  $\geq 48$ ) use a locking plate (→ [fig. 16](#)).

Lock washers, locking clips and locking plates are simple, stable and reliable fastening elements which engage a keyway in the shaft or key slot in the adapter sleeve. The washer locks the nut in position when one of the washer tabs is bent into one of the slots on the nut (→ [fig. 17](#)). Locking clips and locking plates are attached to the nut by bolts (→ [figs. 18 and 19](#)).

A locking clip consists of the clip, a hexagonal head bolt in accordance with EN ISO 4017 and a spring-lock washer in accordance with DIN 128 (→ [fig. 15](#)). A locking plate consists of the plate, two hexagonal head bolts and a wire (→ [fig. 16](#)).

The nut and the locking device must be ordered separately. The appropriate locking device is listed in the product tables. KM lock nuts can be locked either with the MB lock

washer listed in the product tables or with a stronger, MB .. A lock washer (→ **product table, page 1318**).

### Lock nuts with an integral locking device

KMK series lock nuts (→ **fig. 20**) have a threaded steel insert in their bore to lock the nut in place on the shaft or adapter sleeve. The threads on the insert match the locknut threads. The insert acts as a pressure plate when a grub screw, which runs through the body of the lock nut, is tightened. (→ **fig. 21**). KMK lock nuts are intended to locate radial bearings in less demanding applications.

KMK lock nuts should not be used on shafts with a keyway or on adapter sleeves with a key

slot. The locking device can be damaged if it aligns with a keyway or slot.

### Lock nuts with a locking screw

KMFE series lock nuts (→ **fig. 22**) use an integral grub screw (locking screw) to press the threads on the nut against the threads on a shaft (→ **fig. 23**) or sleeve. Lock nuts in the KMFE series are intended to axially locate CARB toroidal roller bearings, sealed spherical roller bearings and sealed self-aligning ball bearings on a shaft or an adapter sleeve.

KMFE lock nuts should not be used on shafts with a keyway or on adapter sleeves with a key slot. The locking screw can damage the nut if the screw aligns with a keyway or slot.

Fig. 23

### Precision lock nuts with locking pins

KMT and KMTA series precision lock nuts (→ **fig. 24**) have three locking pins equally spaced around the circumference of the nut to lock it onto the shaft. The locking pins are pressed into the shaft thread with grub screws. The end face of each pin is machined to match the shaft thread (→ **fig. 25**). The holes for the locking pins and grub screws are drilled at an angle to the shaft thread to avoid backlash.

SKF KMT and KMTA series precision lock nuts are intended for applications where high precision, simple assembly and reliable locking are required. They should not be used on shafts with a keyway or on adapter sleeves with a key slot. The locking pin can be damaged if it aligns with a keyway or slot.

KMT lock nuts with a thread ranging from 260 to 420 mm (sizes 52 to 84) can be supplied on request. For additional information, contact the SKF application engineering service.

KMTA lock nuts have a full cylindrical outside surface and a different thread pitch than KMT nuts for some sizes. They are intended primarily for applications where space is limited. The nut can be used to establish a gap-type seal.

### Precision lock nuts with axial locking screws

Precision lock nuts in the KMD series (→ **fig. 26**) are two-piece nuts connected by axial locking screws. Once the lock nut is in place against the component, the locking screws are tightened. This pulls the rear threads forward, locking the nut in place (→ **fig. 27**).

Lock nuts are locked on the shaft (sleeve) by friction. The friction, and therefore the loosening torque, varies as a result of the accuracy of the tightening torque of the grub screw (locking screws), the surface finish of the shaft (sleeve) thread, the amount of lubricant on the thread, etc. The lock nuts should be properly mounted and there should be only a limited amount of lubricant on the thread.			
Sufficient locking for intended bearing applications. Full locking effect is obtained when the nut is not pressed against the locked component.	Sufficient locking for intended bearing applications.	Sufficient locking for precision and general bearing applications.	

### Installation and removal

Except for KMTA lock nuts, all SKF lock nuts have slots around their circumference to accommodate a hook or impact spanner. The designations of the appropriate spanners are listed in the product tables. For additional information about spanners, refer to the catalogue *SKF Maintenance and Lubrication Products* or visit [skf.com/mapro](http://skf.com/mapro).

KMTA lock nuts have holes around their circumference and in one side face. They can be tightened with a pin wrench, a pin-type face spanner or a tommy bar. Appropriate spanners in accordance with DIN 1810 are listed in the product tables.

In addition to the slots, KMT lock nuts with a thread  $\leq 75$  mm (size  $\leq 15$ ) have two opposed flats to accommodate a spanner.

All SKF lock nuts can be reused, provided they are not damaged. A new lock washer, locking clip or locking plate should be used each time the corresponding lock nut is installed. KMT(A) and KMD lock nuts are designed for frequent installation and removal.

### HM(E) and N lock nuts with a locking clip or locking plate

The bolts of the locking clips or locking plates must be secured to prevent them from turning. Locking clips are supplied with a spring-lock washer, which must be placed between the bolt and clip. The wire supplied with the locking plate should be put through the holes in the bolt heads and tightened.

### KMK and KMFE lock nuts

A hexagonal wrench is needed to tighten KMK grub screws and KMFE locking screws. Screw sizes are listed in the product tables. The screws should be tightened to the torque value listed in the product tables.

### KMT and KMTA precision lock nuts

#### Locking

KMT and KMTA precision lock nuts should be locked in two phases:

- 1 Tighten the grub screws carefully until the locking pin engages the shaft thread.
- 2 Alternately tighten the grub screws with a torque wrench until the recommended torque value is achieved (→ **product tables**).

#### Adjusting

KMT and KMTA series precision lock nuts are adjustable. The three equally spaced locking pins enable the nut to be accurately positioned at right angles to the shaft or they can be used to adjust for misalignment between the abutment surface and the adjacent component. Adjustments can be made using the following procedure:

- 1 Loosen the grub screw at the position showing the greatest deviation.
- 2 Tighten the two remaining screws equally.
- 3 Retighten the screw that was loosened.
- 4 Check the accuracy of the installation with a dial gauge.
- 5 Repeat the procedure if the result is not adequate.

#### Removal

When removing KMT and KMTA lock nuts, the locking pins can still engage the shaft thread even after the grub screws have been loosened. Using a rubber hammer, tap the nut lightly in the vicinity of the pins to disengage the pins from the shaft.

### KMD precision lock nuts

KMD lock nuts are supplied with the locking screws gently tightened and with a protector between the front and rear part of the lock nut. KMD lock nuts should be installed according to the following procedure:

- 1** Loosen the locking screws half a turn.  
Do not remove them.
- 2** Remove the protector between the two halves of the lock nut.
- 3** Press the front and rear halves together and screw the lock nut onto the shaft thread. When the rear half grabs onto the shaft thread, a gap occurs between the two parts.
- 4** Screw the lock nut to its final position on the shaft thread. When tightening the lock nut, put the spanner in the slots on the front half of the nut.
- 5** Alternately tighten the locking screws in a criss-cross pattern until the recommended torque value is obtained (→ **product tables**). Use a hexagonal wrench to tighten the locking screws. Screw sizes are listed in the product tables.

For precision positioning, screw the lock nut to the approximate position on the shaft and tighten the locking screws to half of the recommended tightening torque. Then screw the nut to its final position and fully tighten the locking screws.
